Editorial

The Expensive Psychiatric Scrap Heap

The year 1942 may develop many unforeseen things. But it will certainly not see any reduction in the huge pile of expensive psychiatric wreckage that has been accumulating in our medical backyard. To the physical wrecks accumulated there in the ordinary course of the American Way of Life must be added the constantly increasing increment of mental defense and war derelicts. The pile is growing in size at a rate that bids fair to impede the orderly scientific removal by the medical salvage crews of those who can be reconditioned or rehabilitated. Alcoholism, the industrial speed-up, rejections by the Army and Selective Service boards of neuropsychiatric cases (the fifth most important cause for nonacceptance for full military duty) domestic and business difficulties may be expected to heap Pelion on Ossa, to create one of the gravest problems facing medicine in years. For the mechanism of rehabilitation is all too inadequate to keep up with the rapidly increasing numbers of those who must some way be refitted into the productive structure of society.

We face a condition, not a theory. What condition? In part, this:

In the general military hospitals of the Nation, more than one-half the beds are occupied by patients with nervous and mental diseases, according to Lieut. Col. William C. Porter of the Army Medical Corps. This figure includes veterans' hospitals.

The Army has no provision at present for any sort of limited service for these men after they have partially recovered. They must be kept in the hospital until they are discharged. Colonel Porter estimates that about one-fourth of all the beds in well-established general hospitals in the Army are occupied by such patients continuously.¹ After they are released, then what?

The anxieties and tensions of war and other crises tend to increase alcoholism. With what result? "In Massachusetts, among first admissions to state mental hospitals in 1939, . . . alcohol ranked third as a cause of mental diseases, considerably ahead of syphilis, which ranked sixth."² If this is true in Massachusetts, what is the total for the Nation?

The thirty-first annual report of the National Committee for Mental Hygiene says of the state mental hospitals "The situation . . . is daily becoming more critical and we must act to halt developments that threaten a breakdown of their services. . . . Acute overcrowding, poor sanitation, dilapidated buildings, fire hazards, badly fed and poorly clothed patients, exposure to dangerous infections, shocking shortages of medical and nursing personnel, lack of essential therapies—the catalogue . . . is a melancholy one. There is an estimated deficit of 150,000 beds . . . long waiting lists of patients,

¹ New York Times, Aug. 21, 1941.

² Quart. J. Stud. Alcohol 2: No. 2 (Sept.) 1941.

many of whom languish in jails for want of hospital facilities." This condition of affairs may in part be traced to economies of the recent depression and is now further threatened by the induction of professional personnel into the armed forces and by state budget restrictions.

The annual cost in public funds to maintain even such inadequate facilities as there are is nearly \$200,000,000, but only about \$5,000,000 a year is allotted to the support of mental hygiene clinics to prevent the commitment of such mentally ill patients, according to the Public Health Reports.³ This same source alleges that many cities of 50,000 to 100,000 population have no qualified psychiatrist in practice and that "if they were distributed evenly according to population . . . would provide one psychiatrist to every 57,247 persons in the country" Well, in part, those are the conditions, believe it or not.

Perhaps the lack of sufficient properly qualified medical personnel can be rectified in time. Perhaps the general practitioners, or at least many of them, can be re-educated to a better knowledge of how to understand and to treat these mental wrecks. Toward this end the JOURNAL plans to publish from time to time articles on mental health which will be of particular interest to the general practitioner.

Here and there "mental hygiene clinics are springing up, and in these child guid-

ance and habits are being stressed. The adult mental hygiene clinic appears to offer the most practical value." Family care of some patients has been held to be safe for the community by Horatio M. Pollock, Ph.D., of the State Department of Mental Hygiene, writing in the October, 1941, issue of *Mental Hygiene*. And it is well that some method of care for the psychoneurotic other than hospitalization should be receiving proper study and evaluation.

A hospital plant "involves a minimum outlay of millions, \$5,000,000 being about the average figure for a 2,000 bed hospital. The annual maintenance cost . . . is approximately \$800,000, and an attempt should be made to find less expensive methods of controlling mental diseases."⁴

Is it not time for the various state medical societies and other groups interested in mental hygiene to appoint, if they have not already done so, hard-boiled, financially alert, and practical-minded committees on mental hygiene to study, in collaboration with civil agencies, the question of the best methods by which the urgent problems of the mentally ill can be solved inexpensively, rationally, practically, and in a manner realistically related to the inevitable lowered standard of living implicit in the Federal Tax program?

How Long?

In a recently published volume, *Plain Words About Venereal Disease*, Surgeon General Thomas Parran and his assistant, Dr. R. A. Vonderlehr, discuss the problem of venereal disease in the Army and Navy. Medical men have for many years advocated dealing with syphilis and gonorrhea realistically, at the source, as any other infectious disease is dealt with. But because of the fact that the source of these infections, arising in prostitution and venery, is either profitable or pleasurable or both, progress has been

much retarded. Free and factual discussion has been discouraged by religious taboos and sabotaged by those who could reap huge profits from the exploitation of sexual intercourse as long as they could be protected from too much interference in their business by constituted authority, itself often not above sharing generously in the proceeds of the traffic, as well as by the ignorance and fear of the customers.

It is, therefore, a significant and practical advance when the New York

*Times*¹ discusses editorially the question of control of venereal disease in the armed forces.

"Prostitution is the crux of the problem presented. Wherever soldiers, sailors, and defense workers are mobilized the prostitutes are mobilized too. They settle down in shacks and houses. They come in trailers. They are highly organized. They account for 25 per cent of all cases of syphilis in ordinary times and now for 75 per cent around camps and industries. Our tendency to treat syphilis and gonorrhea not so much as diseases but as the wages of sin partly accounts for the squeamishness of local communities to deal with the problem of prostitution drastically. Army and Navy officers have been little better. Despite all the evidence, they prefer regulation and inspection to suppression."

The *Times* is a family newspaper. Families have sons in the armed forces and daughters in the community. Syphilis and gonorrhea are an individual and family concern. Both can be controlled if not eradicated. The knowledge and the means are available.

It is true, as the *Times* points out, that honest difference of opinion exists as to the respective merits of regulation and suppression. But this is a minor matter. The important thing is a body of public opinion, a body of family concern, which shall demand, and get, action based on available modern knowledge to remedy an absurd, stupid, and medieval tolerance of infectious diseases no different except in their symptoms and the manner of their acquisition from tuberculosis, leprosy, or typhoid.

By such editorial comment as that to which we refer, the *Times* is initiating a powerful educational campaign in the place where it will do most good—namely, the home. Of the officers of the armed forces it says:

"Their problem is difficult, because prostitution does not stand by itself; it is part of a complex in which local poli-

ticians, gangsters, real estate agents, a few corrupt physicians who issue certificates of good health at a price, and sometimes the police, are involved."

This places squarely in the laps of the local voters a responsibility to see that local police and health and legislative authorities get on the job and stay on it. Neither Washington nor the Army or Navy can accomplish much without the help of local authorities backed by all the power of the will of the locality that these diseases be cleaned up.

Sharp issue is taken by the *Journal of the American Medical Association* for November 29 with charges contained in a publicity article on the new book, *Plain Words About Venereal Disease*, and with some of the charges in the book itself. The *Journal* says that there seems to be every reason to believe that the venereal incidence in the Army is steadily declining, notwithstanding charges to the contrary in the publicity article and in the book.

"Meanwhile," says the *Journal*, "the Army Medical Department, confident that it is exerting every effort to make its control program effective, lists this outline of its procedures:

"(a) Physical examinations to prevent the induction into the service of selectees infected with venereal diseases.

"(b) Education of the soldiers concerning the dangers of venereal diseases and advice as to the desirability of continence.

"(c) Provision of prophylactic facilities for those who expose themselves to the risk of infection.

"(d) Regular monthly physical inspection of troops to detect infected individuals.

"(e) Thorough treatment until all men who become infected are cured.

"(f) Isolation of venereal disease patients during the infective stages.

"(g) Disciplinary measures for soldiers who become incapacitated because of venereal diseases, unless innocently acquired.

"(h) Cooperation with the Bureau of Medicine and Surgery, U. S. Navy; the

¹ Syphilis and Defense, November 29, 1941, page 16.

U. S. Public Health Service; the Division of Medical Sciences, National Research Council; the American Social Hygiene Association; etc.

"(i) The reporting to the responsible civil health authorities of known civilian sources from which soldiers are infected, in order that such sources may be traced and eliminated.

"(j) The agreement with the U. S. Public Health Service whereby the latter, working through state and local agencies, has undertaken to eliminate civilian sources of venereal infection in extramilitary areas.

"(k) The May law which can be invoked when—and preferably, as all leaders agree—only when existing civilian agencies responsible for the elimination of prostitutes in extramilitary areas fail to do so.

"Plain Words About Venereal Disease

tells of some plague spots—particularly in larger cities of the South and Southwest—where segregated prostitution still prevails. The charge is made that 80 per cent of commanding officers are opposed to repression of prostitution and favor regulation (page 109). Yet actual newspaper accounts from many areas show that many officers are taking their responsibility most seriously. Perhaps the nation as a whole is not too ready to cede more of its obligations to federal control."

How long will it be before the several communities of the Nation will prepare and enforce, locally, as comprehensive a program to protect themselves as the Army and Navy are putting into practice right now?

In our view, the will to be rid of the sources of these infections must exist before any program can be effective.

A Call to Service

DR. FRANK H. LAHEY

President of the American Medical Association

The establishment by the government of a Procurement and Assignment Agency properly places the responsibility for obtaining medical personnel in the hands of the medical profession. The success of this agency depends entirely on a few basic features: the complete cooperation of medicine in what even the most doubting must now admit is a truly national emergency; an unqualified willingness to serve the country however, wherever and whenever required; and a firm purpose to establish the fact that medicine intends to maintain its place in the forefront as it always has when a patriotic example is of such significance.

THE DIRECT SUPRAVESICAL EXTRAPERITONEAL CESAREAN SECTION

RAYMOND J. PIERI, M.D., and FRANCIS R. IRVING, M.D., Syracuse, New York

ANY discussion of the modern evolution of the truly extraperitoneal approach to the pregnant uterus, regardless of the technic employed, would be incomplete without at least an outline of the more ancient history of cesarean section.

The delivery of an infant through the abdominal wall of its mother is probably centuries older than recorded history. It is likely that even the ancient Egyptians may have been aware of the procedure, and it is known that during many centuries of antiquity such operations were not rarely performed upon pregnant women who were presumably dying or already dead. Indeed, Numa Pompilius¹ (715 B.C.), the second king of Rome, decreed it unlawful to bury a pregnant woman before extraction of the fetus by abdominal section. Subsequently, the Roman law² made the latter procedure compulsory throughout ancient Italy. While many instances are recorded of living children being thus born,³ no claims are made that any mothers survived the ordeal.

Before 140 B.C. the ancient Jewish laws,⁴ according to the Mishnejoth, made mention of the operation, while later (400 A.D.) the Talmud contained references to two types of abdominal delivery.

Pickrell⁵ states that the *Chirurgis Guidonis de Cauliaco* (1363) was the first medical work to contain an account of the actual operation, while the first authentic case in which abdominal delivery was performed on the living woman was in 1491. Nearly a century later (1581) Rousset, in a published monograph, claimed successful abdominal delivery in 14 cases. After Rousset and his claims of success, there was manifest in Europe a gradual increase in the number of accoucheurs who resorted to this means of delivery in complicated cases of dystocia. It must be remembered that advanced disease and deformity of the bony pelvis⁶ were then more frequently encountered than at present. Vitamin and dietetic deficiencies and their relation to skeletal maldevelopment were still unknown.

In his excellent historical review Barry⁷ mentions the mortality rates following cesarean section reported during the nineteenth century from various parts of the scientific world. These ranged from 52 per cent (United States) and 84 per cent (England) to nearly 100 per cent (France and Austria) up to the year 1869. Lister's immortal work⁸ did not appear until 1867. Modern aseptic technic in obstetrics was still unborn. So was modern surgery. All laparotomies yielded a frightfully fatal toll.

In spite of these abhorrent statistics, and the opposition to abdominal delivery which such dire results inevitably produced, cesarean section still remained, in some cases, the only alternative to destruction of the living child by craniotomy. Aversion of the obstetric surgeon for the latter operation, plus its condemnation by the Catholic Church, slowly overcame the deserved prejudices against delivery by abdominal section and encouraged repeated attempts at betterment of the surgical technic.

Sänger⁹ (1882), observing the principles of asepsis and by the use of sutures in the uterus, contributed much toward improvement of the operation. But with the passing years even the most refined skill in the performance of the original classic operation in unselected cases yielded, as it still yields, a high mortality rate (1 to 10 per cent).

It is not surprising, therefore, that other types of section were devised. Porro¹⁰ (1876) had introduced supravaginal amputation of the uterus after delivery of the child. This was followed by a decided decrease in the number of fatal results, especially in infected cases.

The first premeditated low cervical section had been performed (DeLee)¹¹ by Osiander, of Goettingen, in 1805, and was repeated by the same operator in 1806. Jeorg¹² emulated Osiander. While none of the patients survived these original procedures, the idea of incising the lower segment of the uterus was the forerunner of the present-day type of low cervical operation.

Not until a century later did Frank¹³ (1907), of Cologne, recalling Osiander's work, report his "exclusion" operation, whereby he entered the abdominal cavity by a transverse

suprapubic incision and then sutured the parietal peritoneum to the uterine peritoneum above the level of the lower uterine segment. He thus excluded the upper portion of the abdomen from the operative field. Delivery was then accomplished through a transverse uterine incision.

To Sellheim¹⁴ and his prolific pen must go most of the credit for extensive studies and reports of the surgical anatomy of the pelvis. He found that the firm attachment of the peritoneum to the prevesical fascia is limited, for the most part, to the summit of the bladder, while laterally this adherence becomes less and less firm. Likewise, in 1910 he noted the advantages of operating through the low, noncontractile portion of the uterus. He devised several low cervical (intraperitoneal or transperitoneal) procedures, the so-called fourth operation of Sellheim providing the fundamental steps of the present laparotomectomy of DeLee, Franz, Optiz, Krönig, and Beck.

But none of these low operations—each of them greatly superior to the old, now almost obsolete, classic operation in which the contractile body of the uterus was incised—could completely overcome the lurking dread of peritonitis. Some danger of contamination as a result of uterine “spill” remained as a

constant threat. This was especially true in the presence of infection, no matter how meticulously the exposed upper part of the abdomen was artificially isolated from the operative field. It is precisely in the infected case that extraperitoneal delivery becomes a source of consolation to the surgeon.

To devise a truly extraperitoneal operation that can be performed with reasonable facility has long been the dream of the obstetric surgeon. As early as 1820 Ritgen¹⁵ attempted to enter the lower uterine segment by incising above and parallel to the right Pouparts' ligament. By displacing the intact peritoneum upward and the bladder laterally he exposed and incised the uterus, but such severe hemorrhage ensued that the operation, gastrolytotomy, was abandoned and completed by the classic route. According to Dewees,¹⁶ Physick had recommended a similar operation in 1824 but had never attempted it.

The year 1909 brought forth the two extraperitoneal operations of Doderlein¹⁷ and Latzko.¹⁸ The aim of each of these procedures is to reach the passive segment of the uterus by bluntly dissecting the peritoneum upward over the upper left of the bladder while that organ is pulled downward and to the right. Thus, there is exposed about one-half of the field originally covered by the latter organ. A longitudinal incision into

the uterus then serves as a means of delivery of the child.

Aldrich¹⁹ still further modified this approach (1937) by incising the fascia of the perivesical capsule in the midline and retracting the bladder sufficiently to enter the uterovesical space. In the case of a large baby the space made available for delivery in these operations, however, sometimes invited great risk of injury to maternal structures and made delivery a formidable procedure.

In the United States, until 1939, Davis,²⁰ Burns,²¹ Steele,²² Norton,²³ and Aldridge had performed collectively what was probably the largest number of cases delivered by the Latzko or modified Latzko method. In January of that year Dr. Edward G. Waters²³ reported a series of 32 cases in which he had successfully accomplished extraperitoneal delivery in accordance with a new and apparently safer modification of operative technic. To demonstrate the surgical simplicity of this latter operation, to stress to the obstetric surgeon that it is both rational and practicable, and to emphasize its advantages are the purposes of this presentation.

This so-called direct supravescical operation is based upon certain well-established anatomic facts.

The first essential, briefly expressed, is concerned with the distribution of the fascia endopelvina.²⁴⁻²⁵ The latter (pelvic fascia) is practically a continuation of the transversalis fascia, a thin, avascular aponeurosis which forms a line of cleavage between the inner surface of the transversus abdominis muscles and the extraperitoneal fat. The transversalis fascia lines the entire abdominal wall and in the midline separates the peritoneum from the posterior sheath of the recti muscles from above downward to a short distance below the navel. Here, the posterior rectus sheath terminates in a definite margin (linea semicircularis). From this point the transversalis fascia, lying now between the peritoneum and the posterior surface of the recti, descends to become more or less continuous with the pelvic fascia. The main sheet of the pelvic fascia gives off four layers, one a laminated layer that encloses the bladder (fascia vesicae or perivesical fascia) and a second that envelops the uterus (fascia uteri). A third layer forms the vesicovaginal septum, while the fourth forms the rectovaginal septum.

It is well known to all who are familiar with surgery of the lower uterine segment

FIG. 3. Pregnancy at term. Floating head. The bladder is distended with solution. A, parietal peritoneum; B, bladder; E, extraperitoneal space; P, uterovesical space; S, lower segment; V, visceral peritoneum.

that the peritoneum covering the uterovesical space (see Fig. 1) is freely movable and that the bladder can be separated from the uterus bloodlessly and with remarkable ease between the respective fascial coverings of these two organs. This loose attachment between peritoneum, bladder, and lower uterine segment, greatly increased during pregnancy, permits enlargement of the gravid uterus and proper function of the bladder (see Fig. 2), which obviously could not distend if restricted by rigid fascial or peritoneal bands. Only at the summit and posterior aspect of the bladder are the peritoneum and perivesical fascia intimately adherent to each other. This close adherence is limited to a relatively small area.

Cognizant of these factors, we have performed a series of extraperitoneal operations employing a technic that is practically identical with that demonstrated by Waters.

After the usual preoperative preparation for cesarean section, a retention catheter is connected to an ordinary irrigator containing 500 cc. of sterile indigo-carmin or methylene blue solution, of which about one-half or more is allowed to flow into the bladder (Fig. 3).

Distended in this manner, the bladder carries with it the adherent peritoneum upward into the superficial portion of the proposed operative area (the extraperitoneal space). This facilitates the task of dissection.

R.J.P.

FIG. 1. Relation of peritoneum to pelvic organs in nonpregnant state. A, parietal peritoneum; E, extraperitoneal space; P, uterovesical space.

suprapubic incision and then sutured the parietal peritoneum to the uterine peritoneum above the level of the lower uterine segment. He thus excluded the upper portion of the abdomen from the operative field. Delivery was then accomplished through a transverse uterine incision.

To Sellheim¹⁴ and his prolific pen must go most of the credit for extensive studies and reports of the surgical anatomy of the pelvis. He found that the firm attachment of the peritoneum to the prevesical fascia is limited, for the most part, to the summit of the bladder, while laterally this adherence becomes less and less firm. Likewise, in 1910 he noted the advantages of operating through the low, noncontractile portion of the uterus. He devised several low cervical (intraperitoneal or transperitoneal) procedures, the so-called fourth operation of Sellheim providing the fundamental steps of the present laparotrachelotomy of DeLee, Franz, Optiz, Kronig, and Beck.

But none of these low operations—each of them greatly superior to the old, now almost obsolete, classic operation in which the contractile body of the uterus was incised—could completely overcome the lurking dread of peritonitis. Some danger of contamination as a result of uterine “spill” remained as a

FIG. 8. As dissection continues the divested bladder drops downward. More and more of the lower segment is thus exposed.

bladder fundus permits exposure of a portion of the lower uterine segment as the peritoneal fold or "sac" is carefully sought and identified (Fig. 6).

The bladder is now emptied, and under direct vision the left index finger is introduced into the vesico-uterine space below the exposed peritoneal fold and is gradually insinuated toward the operator between the lower uterine segment and the bladder. With slight traction upward (Fig. 7) the edge of the peritoneal plica is placed on a stretch. The posterior perivesical fascia is now in front of the finger and is clearly visible "tugging" between the edge of the peritoneal fold and the bladder. Incision of this fascia without damage to peritoneum is now meticulously accomplished from left to right, the divested bladder dropping downward as it is freed in this fashion (Fig. 8) while the severed fascia adheres to the peritoneal fold above. In some cases a prominent median umbilical ligament (urachus) is encountered, apprising the operator of the location of the midline. The dissection, however, traverses the entire adherent area. Experience has shown that preservation of the urachus is irrelevant and, therefore, optional. Any bleeding vessels injured during the dissection are easily ligated with fine catgut. Shortly, the peritoneal plica above is entirely freed from the bladder below. Between them in the background (Fig. 9) lies the lower uterine segment. Excellent exposure of the latter is secured, using a wide, curved retractor to hold the

FIG. 9. The uterovesical fold of peritoneum is completely separated from the bladder, which is now held behind the pubes by means of a retractor.

bladder downward, a lateral retractor on each side, and a fourth to retract the freed and intact vesico-uterine fold above. The operative field is spacious, bloodless, and completely extraperitoneal. Even additional space, seldom necessary, may be created by bluntly separating upward more of the peritoneum

FIG. 4. (After Waters) A T-shaped incision is made over the bladder down to muscularis. The peritoneal attachment is above the transverse portion of the incision.

FIG. 5. Dissection of the perivesical fascia upward carries with it the adherent peritoneum.

The operator works usually from the patient's right side. Through either a low left paramedian incision or a Pfannenstiel incision the recti muscles are separated and retracted laterally from the midline, exposing the intact transversalis fascia between the linea semicircularis above and the pubes be-

FIG. 6. As the peritoneum and fascia are dissected upward, the left top of the bladder is carefully pushed downward, revealing LS (the lower uterine segment) and the left margin of the peritoneal "sac."

low. The area thus exposed demarcates the proposed operative field. The outline of the distended bladder is visible through the intact transversalis fascia, which is now carefully incised vertically to expose the underlying and more closely woven layers of the perivesical capsule of fascia.

A short (1 or 1½ inch) vertical incision through the laminations of this fascia down to the bladder muscularis is now cautiously made in the midline, beginning a few centimeters below the bladder fundus in order to avoid the peritoneum. Various small blood vessels on the surface of the muscularis aid as a landmark at this stage of the procedure. With the closed scissors or with the knife handle the fascia is freed from muscularis and incised transversely. The bladder muscularis has now partially been exposed by two incisions not unlike the letter T (Fig. 4) made through the anterior perivesical fascia. Separation of the fascia above the transverse incision (Fig. 5) carries upward with it the peritoneum. Meanwhile, with the aid of a sponge, separation of the bladder downward is begun over the upper left border of this organ, seeking the margin of the vesico-uterine fold. This step is facilitated by previous labor and by the usual dextrorotation of the pregnant uterus, which makes the left portion of the vesico-uterine space more shallow. Here, the loose areolar tissue lateral to the

For purposes of comparison, all of the so-called "clean" cases, including the four elective operations, are tabulated in Table 1. It will be seen from this table that the results following the extraperitoneal operation in this group compare favorably with those that might be expected to follow any transperitoneal lower segment operation in similar cases. Case 1 was a primipara with an imparted shoulder presentation. A purulent infection of the incision was the sole cause of her longer-than-average stay in the hospital. The recovery of the staphylococcus organism by culture during operation in Case 6 did not affect convalescence.

The cases that were considered as potentially infected are included with those that were assumed to be actually infected. These are listed in Table 2. It is evident from this table that no serious complication was encountered in spite of positive culture reports in several instances. Aside from the wound infections, only 1 case presented any abdominal signs. This was Case 5, in which marked abdominal distention was noted on the second day. Prompt relief followed the administration of prostigmin and a simple enema. Eight of this group were morbid postoperatively, a not unexpected sequel to their febrile preoperative condition.

During delivery of the baby the preservation of the integrity of the peritoneal fold

and of the incision in the lower uterine segment was remarkable. The former was not injured, while in only 1 case was extension of the uterine incision observed, although version and extraction were performed in 3 cases.

Conclusions

1. Twenty cases of direct supravaginal extraperitoneal cesarean section are presented.

2. There was no maternal or fetal mortality in this series.

3. The results in these cases, 9 of which were preoperatively termed actually or potentially infected, were uniformly good.

4. The technic of the operation proved to be not too difficult, although meticulous care had to be taken in the separation of bladder fascia from bladder muscularis.

5. The birth opening made available by following this technic proves to be larger and more accessible than that secured by the Latzko or modified Latzko method.

6. With a not too difficult operation at his disposal the obstetric surgeon can, with greater equanimity, allow the borderline case a longer test of labor.

7. Especially in infected cases, it is hoped that other hands will further demonstrate the safety and satisfactory results of what we believe to be an operation that will enable the accoucheur to reduce the hazards in this type of case.

FIG. 10. Additional retractors expose a wide area of the lower segment. The proposed crescentic incision is made as indicated (see text).

from the anterior surface of the lower segment.

The uterine incision is started as a "nick" in the lower segment about an inch above the bladder retractor. Culture of the amniotic fluid is routine. With bandage scissors the incision, as recommended by Dr. Waters, is carried widely toward each side, curving the ends upward to a level 1 to 1½ inches above the original nick. This creates a crescentic aperture, the curved diameter (Fig. 10) of which makes possible a much larger opening than could be provided by any straight incision similarly located. The spill is removed by suction.

In vertex presentations, either the face or the vertex is brought to the front, delivery being accomplished manually or with forceps exactly as in laparotrachelotomy, or (as also recommended by Waters) a single blade of the instruments, aided by suprafundal pressure, may be used as a vectis to raise the head out of the pelvis. Simultaneously, ergotrate is administered intravenously, thus usually obviating the necessity of manual extraction of the placenta and membranes, a maneuver that is especially undesirable in the presence of infection. Several T-shaped clamps are used to grasp the edges of the uterine wound. The operative field is sponged dry, and the uterine incision is closed by two layers of running chromic No. 1. sutures. The second layer (Lembert) inverts the first layer and effectively seals the operative field from the uterine cavity and vagina.

Using warm moist sponges, inspection is

carefully made for bleeding points and damage to the bladder, which is refilled meanwhile if necessary. The transversalis fascia over the bladder is sutured, and the uterovesical space is drained with rubber tissue. The peritoneal fold is then allowed to fall into place (but is not sutured). Two or three sutures are used to coaptate the separated recti muscles. Ordinarily, no retention sutures are considered necessary, the closure being completed with a continuous chromic No. 2 suture in the rectus fascia and clips to the skin.

The catheter is permitted to remain in the bladder forty-eight hours, while the rubber drain, depending upon the degree of infection present, is not removed for three to five days.

Summary of Results in 20 Cases

During the ten months preceding this report we have performed the operation as above described upon a series of 20 patients without maternal or fetal mortality.

The operating time is of interest, varying from ninety minutes to forty-two minutes. In general, the earlier operations consumed more time because of inexperience with the technic. With 3 exceptions in which nitrous oxide, oxygen, and ether were employed, spinal anesthesia was chosen. In 5 cases the peritoneal cavity was inadvertently opened during dissection but before incising the uterus. In each instance the opening was immediately tied off (not sutured) before continuing the operation. In 2 instances the bladder was entered and repaired at once. In neither case did any vesical complication follow.

Fifteen of our cases were primiparas and 5 were multiparas. Sixteen had been in labor for periods that varied from eleven hours to ninety-six hours. Four operations were performed as elective procedures prior to the onset of labor. Three of these were upon women each of whom had been delivered once previously by laparotrachelotomy. The fourth was an elderly primipara with a breech presentation near term and a borderline pelvis.

Of the 16 patients who had been in labor, 7 were "clean" cases and 9 were actually or potentially infected at the time of operation. Vaginal examinations during labor or ruptured membranes of over ten hours' duration were the criteria for our classification of potential infection. The presence of fever was the additional criterion for assuming the presence of actual infection.

A PLEA FOR THE EARLIER DIAGNOSIS OF RECTAL CANCER

An Analysis of 108 Clinic Patients

RALPH R. BRAUND, M.D., and GEORGE E. BINKLEY, M.B. (Tor.) F.A.C.S.,
New York City

PROGRESS during the last twenty-five years in the treatment of cancer of the rectum is encouraging to all students of oncology. No greater strides have been made in the entire field of cancer therapy. Improved pre-operative and postoperative management has given the surgeon better control of the metabolic processes of patients. This, together with improvements in surgical technic, has resulted not only in a lower operative mortality but also in an increased operability rate and a higher percentage of five-year survivals.

Twenty-five years ago the operability in the larger private clinics did not exceed 30 per cent, with an immediate mortality of 20 per cent plus. Today, in some private clinics the operability rate for rectal cancer has reached the high average figure of 60 per cent, with an operative mortality under 10 per cent. More encouraging is the corresponding increase in the number of five-year survivals from 26 per cent in 1925 to 60 per cent plus in 1940. Unfortunately, however, the early diagnosis of cancer of the rectum has not kept pace with the advances made in treatment.

In the free clinic of the Memorial Hospital so many new patients are seen with far-advanced and hopelessly incurable cancer of the rectum that we thought it would be of interest to determine the reasons for the delay in these patients presenting themselves for treatment. It is hoped that by presenting these reasons, together with the symptomatology and proper methods of examination, the general practitioner may become more "cancer conscious" and arrive at the proper diagnosis without undue delay.

The general practitioner has the greatest opportunity to recognize the disease in the early stages. The extensive educational program for the laity conducted by radio, press, and lecture will be of no avail if physicians fail to make an early diagnosis of a cancer and fail to give adequate advice.

Detailed histories were taken on 108 unselected patients with cancer of the rectum who were admitted to the rectal clinic between July 1, 1939, and December 31, 1940.

From the Colon and Rectal Service of Memorial Hospital for the Treatment of Cancer and Allied Diseases.

We were interested chiefly in family history, symptomatology, time interval from onset of symptoms until they sought medical advice, type of examination and treatment received prior to admission, and lapse of time before reference to the clinic.

Family History

It is difficult to obtain an accurate family history of cancer from many patients. This is true when dealing with a group, many of whom are foreign born and have little knowledge of the cause of death of members of their families. The feeling that cancer stigmatizes a family is also encountered. Patients may stoutly deny such history and then, after reflecting that truth might affect the method of treatment, report at their next clinic visit instances of cancer in the family. Thirty-one, or 28.9 per cent, of our patients gave a family history of cancer in 41 relatives, 10 of whom had cancer of the rectum (Table 1).

Symptomatology

Symptoms usually described in textbooks as offensive, purulent, bloody stool, alternate diarrhea and constipation, pain, weight loss, intestinal obstruction, tenesmus, wasting, and cachexia are not early manifestations of the disease, though they are too often present before the diagnosis of rectal cancer is made. In our experience they are invariably associated with large advanced lesions, frequently inoperable and incurable.

To record, in sequence, symptoms caused by carcinoma of the rectum is difficult if one desires to emphasize early manifestations of the disease. Confusion is added by the fact that many intestinal conditions produce the clinical picture of carcinoma. Unfortunately, the early, almost unnoticed changes in bowel habits produced by rectal cancer often mislead the physician because they are easily relieved by bland diets and mineral oil. The early symptoms of rectal cancer may be summed up by the statement that any mild symptom that is sufficient to attract the patient's attention to this part of his anatomy may be a symptom of cancer. In these patients the first recognizable symptoms of their rectal

Discussion

Dr. E. G. Waters, *New York City*—It must be apparent to one who considers the anatomy of the pelvis, and especially fascial distribution, that there are but two feasible anatomic approaches to the uterus by an extraperitoneal route. One is a paravesical approach with lateral displacement of the bladder, and the other is a supravesical approach.

The paravesical approach was first proposed in

1806 by Joerg and was first performed by Ritgen in 1821. Thomas in 1871 and Asa B. Davis in 1915 and 1924 reported experiences with an operation embodying the same approach. In 1909 Latzko again made a paravesical approach to the uterus but entered the abdomen in a totally different manner. He used a left lower rectus approach, distending the bladder to outline it and to reach the extraperitoneal space, thus avoiding the inguinal incisions of the other operators. The supravesical approach was first proposed by Physick in 1824, and unsuccessful attempts were made to develop a satisfactory technic in 1908 by Frank and in 1909 by Sellheim.

The first series of 32 cases which I reported in 1939, illustrating anatomic principles not previously given sufficient attention, represents a utilization of the second or supravesical type of approach. I wish to compliment Drs. Pieri and Irving on the excellence of their presentation and for the pictures we have seen here. We are convinced from our own experience with the operation that it fills a place in operative obstetrics for the management of the potentially and actually infected case in labor better than any other procedure with which we have had experience. We have, at this time, more than 150 patients operated on by the supravesical approach according to the technic I first outlined in 1937, with but 1 death. As a matter of fact, mortality in this group of cases, representing the worst risks where the highest mortality figures might be expected, actually shows a lower mortality rate than for all other forms of cesarean sections performed on so-called "clean cases."

Obviously, this is not an operation for the tyro or the occasional obstetric operator. It demands a theoretic and working knowledge of pelvic anatomy, especially of the investing endopelvic fascia. It has completely displaced Porro, Portes, and similar operations in our clinic. Many "borderline" cases have avoided cesarean operations by getting more adequate trial labors. With an operation of this sort in reserve, one needs to hasten less. We confidently believe that further experience by those whose combination of pelvic anatomic knowledge, operative ability, and obstetric judgment is good will prove the operation a safe procedure for use on the worst cases we encounter.

The experiences of Dr. Eisaman in Pittsburgh, Drs. Irving and Pieri, and others now employing this technic seem to justify this confidence.

A Vicar had been beaten badly on the golf links by a parishioner thirty years his senior, and he was rather disgruntled. "Cheer up," his opponent said. "Remember, you win at

the finish. You'll probably be burying me some day."

"Even then," said the Vicar, "it will be your hole."
—Canadian Doctor

Mucus.—Mucus is a common finding in conditions producing prolonged frequency of stool. This too often leads to the diagnosis of colitis when the real disease is a precancerous polyp or a carcinoma. The mucus resulting from carcinoma is usually accompanied by frequent stools, pus, blood, and foul-smelling flatus. It is indicative of ulceration and advanced disease. The presence of mucus was noted by 31 patients at the time of admission. In only 1 case was it the first symptom noted.

Other Symptoms.—Other symptoms frequently seen have been summarized in Table 2 and need not be taken up in detail. They are all evidence of well-established disease.

Duration of Disease Before Treatment

The duration of disease for each patient was computed from the onset of symptoms that could be interpreted as due to cancer. All patients considered were admitted to the free clinic of the Memorial Hospital. In some instances they had delayed seeking medical care because of their inability to pay for private medical service. Others delayed because they failed to recognize the seriousness of their symptoms; still others, because they suspected the presence of cancer and feared the truth. The average interval from onset of symptoms to seeing a physician was eight and nine-tenths months. Rosser⁵ reports an average time from onset of symptoms to operation of ten months. Shedden⁶ states that 63 per cent of his 111 cases delayed four or more months before diagnosis was made and that 41 per cent delayed seeking medical opinion two months or more. Brindley,² in a review of 167 cases, finds an average duration of symptoms before examination of nine months, and in those patients with inoperable lesions it averaged fourteen months.

Eight of our 108 patients came directly to the clinic and had not seen a physician prior to their admission. Of the remaining 100 patients, an accurate diagnosis was made early in 25, and they were referred to the clinic within one month from the day they first sought medical opinion. In the remaining 75 patients there was an average additional delay of nine and nine-tenths months from the time they sought medical advice until they were referred to the clinic. Analysis of Table 3 indicates that 69.4 per cent of the 108 patients remained untreated for an average of eighteen and eight-tenths months after the onset of symptoms. One-half of

TABLE 3.—DURATION OF DISEASE BEFORE TREATMENT

	Number of Patients	Average Delay, Months
Before seeking medical advice, all patients	108	8.9
Admitted without previous medical advice	8	
Referred within one month after seeking medical advice	25	
Referred later than one month after seeking medical advice	75	
Delay after seeking medical advice before referral to the clinic	75	9.9
Duration of disease before admission	75	18.8

this delay interval was due to the failure of physicians to make the correct diagnosis.

It is the duty of every physician to make a careful rectal examination of every patient who presents himself with a complaint referable to any part of the gastrointestinal tract. The procedure is simple, being easily performed in the office. The only prerequisite for a satisfactory examination is that the bowel must be thoroughly cleansed. This is accomplished by the oral administration of castor oil or licorice powders the day before. Should there be a suspected obstruction, we prefer cleansing the rectum with enemas.

Rectal examination consists of inspection of the perianal skin, palpation of the anal canal and lower rectum with the finger, and inspection of the lower sigmoid, rectum, and anal canal by means of suitable instruments. The preliminary examination may be carried out in the Sims position. By having the patient bear down, the physician is able to palpate the upper limits of the rectum. Sigmoidoscopic examination is performed with the patient in the knee-chest position, the knees separated about 8 inches, the head turned to one side, and the side of the patient's face resting on the examining table. If the face is turned to the right, the left arm and forearm are placed beneath the patient, permitting the patient's left shoulder to rest on the table. This prevents the tendency of the patient to crawl forward during proctoscopy. The back must be flat or scaphoid, never arched. An electrically lighted, well-lubricated sigmoidoscope is passed, and careful inspection is made of the lower sigmoid, rectum, and anal canal. Should a tumor be found, a confirmatory biopsy must be taken in every instance. The presence of streaks of mucus or blood on the wall of the rectum may denote a tumor above the field of vision.

X-ray studies may often fail to reveal the presence of lesions in the rectum proper, even

cancers were, in their order of frequency, blood in the stool, constipation, increase in flatus, diarrhea, pain, and mucus (Table 2).

Blood in the Stool.—Blood in the stool may have its origin in any portion of the alimentary tract and is frequently associated with rectal cancer. Persistent bright blood, unless associated with extreme diarrhea, is indicative of ulcerative pathology below the splenic flexure. Low-lying lesions may produce tarry stools if evacuation is delayed or if the physiologic action of the bowel moves the contents of the ampulla and rectosigmoid upward. Since hemorrhoids may cause bleeding, they sometimes result in an error in diagnosis. Shedden* reports that 36 of 111 cases of carcinoma of the rectum had a previous diagnosis of "piles." The cancer bleeding in the beginning may be only a faint pink in the toilet or on the cleansing paper. In other instances there may be frank hemorrhage of sufficient magnitude to produce ten or more evacuations of nothing but blood during a twenty-four-hour period. The passing of blood with the stool was the first symptom noted by 32 of our patients; 87 of the group had rectal bleeding at some time prior to admission.

Constipation.—The word "constipation" is an indefinite term. By constipation, as an early symptom, we mean a sudden or gradual onset of difficulty in securing a good evacuation where there had previously been soft,

well-formed, daily stools. As the bowel sluggishness progresses, large doses of cathartics are often taken without satisfactory elimination. Rarely have we seen the clinical picture of constipation alternating with diarrhea, a condition so frequently described in textbooks. Fifty-one of our patients complained of constipation as one of the symptoms of their disease; in 30 it was the first symptom.

Flatus.—In 28 patients an appreciable increase in flatus was the first symptom of their disease. It was noted by 47 before admission. Flatus is usually considered dietary, but in an individual eating his customary diet we believe it has definite clinical significance and should lead to a suspicion of neoplasm in the large bowel. It is often an early symptom of rectal cancer and is readily noticed by the patient because of the foul odor due to sloughing of tumor tissue. In 2 patients it was the only symptom at the time of admission and was the cause of their seeking medical aid.

Diarrhea or Frequent Bowel Movements.—Although diarrhea is a common symptom of cancer of the rectum and was noted by 36 of our patients before coming to the clinic, it was the first symptom in only 12 cases. It is usually associated with a large, ulcerated, infected lesion and consists of the frequent passage of mucus, blood, liquid feces, and foul-smelling flatus.

Pain.—Pain from cancer of the rectum is due to any one of three causes or to a combination of the three. Frequent evacuations may produce acute, severe anal pain. There may also be pain or ache referred to the buttocks or over the coccyx and sacrum. The second type of pain produced by partial obstruction is colicky and is relieved by expelling flatus or stool. It comes and goes, being readily produced should the patient be subjected to undue nervous strain. Colicky, cramplike pain is located chiefly in the lower left abdominal quadrant and is more marked with lesions about the rectosigmoid junction. The lumen need be only mildly constricted by an annular or pedunculated lesion to produce such pain. The third type of pain is that produced by invasion or compression of the regional sensory nerves. This is a relatively late symptom and indicates perirectal extension or involvement of the anal canal. The patients describe it in the beginning as an ache in the region of the lower sacrum and coccyx. In the present group of patients only 4 had pain as an initial symptom, while 36 had pain at the time of admission.

Summary

1. The great progress made in the last twenty-five years in the treatment of cancer of the rectum has not been accompanied by a corresponding improvement in making an early diagnosis.

2. Thirty-one of 108 patients gave a definite history of cancer in 41 blood relatives, 10 of whom had cancer of the rectum.

3. The early symptoms of rectal cancer simulate the symptoms of inflammatory disease of the anus and rectum. The symptoms listed here and in the literature are symptoms of unknown pathology that on proper examination may prove to be due to a well-established cancer.

4. The 108 patients sought medical advice on an average of eight and nine-tenths months after the onset of symptoms attributable to their rectal cancer.

5. Of the 100 patients referred by their

family physicians, the disease was diagnosed without undue delay in 25, and they were referred within one month after their first visit. In 75 patients there was an additional average delay of nine and nine-tenths months before they were referred to the clinic. During this delay they received inadequate or improper therapy.

6. The delay in making immediate diagnosis was the result of the physician's failure to make a complete rectal examination or his inability to interpret his findings.

DERMATOLOGY COURSE TO BE GIVEN

A course on dermatology has been arranged by Dr. George M. Mackee, New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University, for the Montgomery County Medical Society. The lectures, to be held at the Elks Club, Amsterdam, New York, on Tuesday evenings at 8:30 P.M., follow:

January 6.—The Modern Conception of Allergy; Its Relation to Dermatology. (Lantern slides.)

Francis Pascher, M.D., instructor in dermatology and syphilology, New York Post-Graduate Medical School, Columbia University, New York City

January 13.—The Diagnosis and Treatment of Common Skin Diseases. (Exclusive of eczema, drug eruptions, cancer and syphilis.)

Laird S. Van Dyck, M.D., associate, Department of Dermatology and Syphilology, New York Post-Graduate Medical School, Columbia University, New York City

January 20.—The Modern Conception of Eczema with Special Reference to Dermatophytosis (Athletes' Foot). (Lantern slides.)

Royal M. Montgomery, M.D., instructor in dermatology and syphilology, New York Post-Graduate Medical School, Columbia University, New York City

January 27.—Drug Eruptions. (Lantern slides.)

E. W. Abramowitz, M.D., associate clinical professor of dermatology and syphilology, New York Post-Graduate Medical School, Columbia University, New York City

February 3.—The Diagnosis and Treatment of Cutaneous Cancer and Precancerous Lesions. (Lantern slides.)

Frank Fraser, M.D., consultant, Department of Dermatology and Syphilology, New York Post-Graduate Medical School, Columbia University, New York City

February 10.—Cutaneous Tuberculosis and Allied Conditions. (Lantern slides.)

Anthony C. Cipollaro, M.D., associate, Department of Dermatology and Syphilology, New York Post-Graduate Medical School, Columbia University, New York City

February 17.—The Diagnosis, Cutaneous Manifestations, and Clinical Course of Syphilis.

Girsch Astrachan, M.D., associate, Department of Dermatology and Syphilology, New York Post-Graduate Medical School, Columbia University, New York City

when quite large. The rectum is capable of holding large quantities of barium and fills so readily that the lesion is often obscured unless the radiologist is especially astute and has been forewarned of the possibility of a low lesion; therefore, x-ray investigation of the terminal parts of the intestinal tract should not be employed prior to sigmoidoscopic examination.

Of the 100 referred patients, 20 had not received a rectal examination, their treatment having been based on their symptoms. Thirty-seven had received a digital examination, which should have been sufficient to make a tentative diagnosis had the examination been properly performed. In this group of patients over 90 per cent of the rectal cancers were within reach of the examining finger. Thirty-four of the group had received a proctoscopic examination prior to admission. Unfortunately, it was delayed in many instances until the disease was far advanced. A confirmatory biopsy had been obtained on only 11 patients. Nine patients had received only an x-ray examination. One patient had received a fluoroscopic examination

without the benefit of a contrast medium. Such an examination is only a gesture and has no diagnostic value (Table 4).

In Table 5 we show the number of physicians seen by each patient before being referred to the clinic. This shopping for medical care by 46 patients who saw from two to five physicians is evidence of the patients' dissatisfaction with, and failure to improve under, the prescribed treatment. In a few instances it was the direct result of being advised that an operation was essential. These patients, having the layman's dread of an operation, would seek further confirmation of its necessity.

Treatment Given Prior to Admission

Table 6 illustrates the numerous varieties of treatments that patients received prior to admission to the clinic. It is quite evident from this list that the diagnosis was in error except for the 6 patients who received inadequate irradiation.

Discussion

Every physician throughout his student and intern training has repeatedly been shown the importance of making a rectal examination, yet the frequency with which this single test is omitted, even in the presence of a history of objective rectal symptoms, is appalling.

From this review of the 108 patients there is conclusive evidence that the diagnosis of rectal cancer in clinic patients is open to great improvement. This improvement may be brought about in two ways: (1) by teaching the laity that any rectal symptom, no matter how mild, may be a symptom of rectal cancer and that all such symptoms should be carefully investigated by a private clinician or in a suitable clinic and that if by chance the symptoms should prove to be caused by cancer the possibility of the patient regaining his normal health is excellent, providing appropriate treatment is undertaken at once; (2) by educating the profession to recognize the danger signals and the importance of a thorough investigation of all rectal symptoms. No physician should ever treat any patient with rectal symptoms without first making a thorough rectal examination. Should a tumor be found, a confirmatory biopsy must be taken in every instance. It is impossible to overestimate the importance of a thorough rectal examination in all cases with rectal and intestinal symptoms.

tages of external application, such as irregular absorption in rate and amount of energy with inconstant, negative, or overdosage effects. Furthermore, in such event one might hope for the constant and safe production of certain of the beneficial physiologic effects already mentioned, e.g., the bactericidal effect, a detoxification effect, a rise in general resistance, etc.

Technic and Dosage

In 1934 Knott and Hancock³³ reported the rather spectacular recovery of 2 apparently moribund cases—1 of septicemia, 1 of brain abscess—following the ultraviolet irradiation of a predetermined amount of the individual's blood and immediate reinjection of that blood. The technic of this method of irradiating blood has since been somewhat modified by Knott and in its modified form is that referred to in this paper as the Knott technic of ultraviolet blood irradiation therapy.

The irradiation of blood with ultraviolet energy with a hemo-irradiator (Fig. 1) is made possible by a combination of three devices: (1) a modified Knott irradiation chamber, (2) an automatic transfusion pump, and (3) a water-cooled mercury-quartz burner.

The automatic transfusion pump allows blood to be pumped by propulsion through rubber tubing and through the Knott chamber at whatever rate is desired, thus carefully controlling the time of exposure to ultraviolet energy of each cubic centimeter of blood as it passes through the chamber. An intermittent exposure is obtained by a rotating shutter interposed between the irradiation chamber and the mercury burner.

The water-cooled type of mercury-quartz burner is used and is fastened approximately 1 cm. from the quartz window of the irradiation chamber through which the blood is pumped.

The clinical application of this combination consists of withdrawing a predetermined amount of venous blood from an individual citrating it (one part 2.5 per cent sodium citrate to five parts blood) and immediately returning it to the same individual through the hemo-irradiator to the vein from which it was withdrawn. The immediate return to the venous circulation of irradiated blood through a closed system obviates the rapid loss from irradiated blood of ultraviolet energy, which occurs if blood is, for example, spread out in open flat receptacles during irradiation.

In using this method it is necessary to be

FIG. 1. Blood irradiation machine (hemo-irradiator). 1. Glass-tipped adapter for the suction or withdrawal end of the rubber tubing system. 2. Glass-tipped adapter for the intravenous or injection end of the system. This is fitted to a needle in the patient's vein. Citrated blood that has just passed through the irradiation chamber (see 4) and thus irradiated is returned to the venous circulation through this adapter. 3. Water-cooled, mercury-quartz burner, the source of high-intensity ultraviolet energy used in irradiating blood. 4. Knott irradiation chamber with quartz window held in contact with mercury-quartz burner. Blood is passed through this chamber, its time of exposure being carefully and automatically adjusted. 5. Hemo-irradiator starting switch. 6. Synchronized transfusion pump. 7. Dial regulating rate of flow and time of exposure. 8. Volt-meter.

sure that three important factors are kept constant. These are: (1) the amount of blood withdrawn and irradiated, (2) the time of exposure to ultraviolet energy, and (3) the intensity and the wavelength of the spectral energy used.

The amount of blood to be used is calculated from the formula $A = KW$, where A is the amount in cubic centimeters to be withdrawn, K is a constant (1.5 in this work), and W is weight expressed in pounds. The amount of blood used rarely exceeded 300 cc., as can readily be seen from the formula.

The time of exposure is considered to be the time required for the passage of 1 cc. of blood through the Knott irradiation chamber while exposed to the ultraviolet emanation

THE KNOTT TECHNIC OF ULTRAVIOLET BLOOD IRRADIATION IN ACUTE PYOGENIC INFECTIONS

A Study of 103 Cases with Clinical Observations on the Effects of a New Therapeutic Agent

GEORGE MILEY, M.D., D.Sc. (MED.), Philadelphia

FOR the past two and one-half years in 103 unselected cases of acute pyogenic infection we have successfully used the Knott technic of ultraviolet blood irradiation therapy as a method of controlling infection. This technic consists of withdrawing and citrating a carefully predetermined amount of a patient's blood and immediately passing it through a hemo-irradiator, a machine that properly irradiates the citrated blood and returns it intravenously to the patient. The hemo-irradiator is by design so constructed as to regulate all dosage factors and, by the precision of its operation, makes the administration of this therapy a safe and efficient procedure. In this paper we shall briefly review a few known biochemical and physiologic effects of ultraviolet energy, give the essential details of the Knott technic, and present the results obtained by us in controlling acute pyogenic infection. A correlation of the observed clinical effects of this therapy with several established biochemical and physiologic effects of ultraviolet will be made wherever this is possible.

The application to physical medicine of ultraviolet energy is not new but has been used for many years as a valuable therapeutic weapon. During these years much has been learned about the various biochemical and physiologic effects of ultraviolet irradiation.

The bactericidal properties of ultraviolet have long been recognized as due to much excellent pioneer work by Downes and Blount,¹ Ward² and, more recently, Coblentz,³ Bayne-Jones,⁴ Wyckoff,⁵ Bachem,⁶ and others.

The detoxification effect of ultraviolet is not generally known by the medical profession and certainly has not been emphasized enough when one considers the fine work of Jodlbauer and von Tappeiner⁷ and Noguchi⁸ early in the century and of Macht,⁹ Schubert,¹⁰ Welch,¹¹ etc., in their studies on detoxification with ultraviolet. Certainly, the inactivation of snake venoms and bacterial toxins are

examples of what may be accomplished by ultraviolet.

Vasodilation is commonly observed wherever ultraviolet energy is used. Studies on this mechanism have been reported by Balderrey and Barkus,¹² T. Lewis,¹³ Krogh,¹⁴ Ellinger,¹⁵ and Kawaguchi.¹⁶

Photosensitization and photodynamic effects must be mentioned because of the many photosensitive chemotherapeutic agents so widely used today. The early work of Jodlbauer and von Tappeiner^{17,18} laid the foundation for recent work by Epstein,¹⁹ Blum,¹⁰ and many others.

The effects on various proteins have been carefully studied and reported by Becker and Szendro,²¹ S. J. Lewis,²² W. C. M. Lewis,²³ Smith,²⁴ and Spiegel-Adolf.^{25,26,27}

The ability of blood irradiated with ultraviolet to absorb oxygen has been investigated by Mayerson and Laurens,^{28,29} Miley,³⁰ and Harris.³¹

Secondary emanatory phenomena have been observed to occur according to Wels,³² Becker and Szendro,²¹ and Rahn.³³

Finally, the effect on general resistance has been the subject of extensive work and has been reviewed carefully by Clark.³⁴ It is common knowledge that certain, as a rule rather low, dosages of externally applied ultraviolet radiations stimulate the general resistance of animals and human beings to infection.

In addition to these selected references, work in this field has been well described by Blum,³⁵ Duggar,³⁶ and Ellis, Wells, and Heyroth.³⁷

In attempting to use these known effects therapeutically, it had been found necessary to depend on external application. Valuable though such a method may be when local effects are desired, it is, nevertheless, subject to many disadvantages contingent upon any attempt to obtain general or systemic effects by the external use of therapeutic agents. It is apparent, then, that if ultraviolet energy could be administered directly to the blood stream (i.e., intravenously) safely and efficiently in easily controlled dosage one might expect the elimination of certain disadvan-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

From the Hahnemann Medical College and Hospital of Philadelphia.

FIG. 2.

FIG. 2. CASE 1. Acute, markedly hemolytic streptococcal oropharyngitis. Ultraviolet blood irradiation therapy was administered immediately on the patient's admission to the hospital because of her rapidly progressing toxic symptoms. Throat cultures taken on admission showed a profuse growth of markedly hemolytic streptococci. Toxic symptoms subsided within twenty-four hours; throat culture became negative in seventy-two hours. She was discharged on the sixth day in excellent condition.

FIG. 3. CASE 2. Incomplete septic abortion; septic endometritis. Seven days of sulfanilamide therapy failed to improve this case, as did four days, withdrawal of sulfanilamide. Twenty-four hours following ultraviolet blood irradiation therapy the patient's toxic symptoms subsided completely and her temperature fell to normal. She convalesced uneventfully and was discharged from the hospital in apparently excellent condition on the twenty-first day, ten days after blood irradiation.

FIG. 3.

lowed up two and a half years later. Nor have there been observed any delayed harmful effects on kidney function or, in fact, on any body function. Although it is not the purpose of this paper to discuss these effects of ultraviolet blood irradiation therapy, it may be added that these findings correspond with those of other workers in this field, e.g., Rebbeck,³⁹ Knott and Hancock,³⁸ and Barrett,⁴⁰ as well as with our own findings in over 300 other individuals who have received this therapy for diseases of a more chronic nature.

Abstracts of Four Typical Case Histories

For the purpose of a more detailed observation of the results of this treatment there follows a series of brief abstracts of case histories of a few selected cases from Table 1.

Case 1 (see Fig. 2).—A woman, aged 31, was referred to the Hahnemann Hospital by Dr. G. Miley. A diagnosis of acute, markedly hemolytic streptococcal oropharyngitis was made.

The patient was admitted on April 4, 1940, complaining of generalized aching and chilliness and sore throat. Her temperature on admission was 102.1 F.

Blood irradiation therapy was instituted at 3:00 P.M. on the admission day. By 6:00 P.M. of the same day her temperature was 101.2 F. She was perspiring profusely. A blood culture taken April 4, 1940, was sterile after ninety-six hours' incubation. A culture from the throat taken April 4, 1940, showed numerous colonies of markedly hemolytic streptococci.

On April 5 and April 6 the patient's temperature still showed a slight rise in the afternoons to peaks of 101 F. on April 5 and 99.6 F. on April 6. A second throat culture taken April 5 still showed markedly hemolytic streptococci, but a culture taken from throat on April 6 showed only a few mildly hemolytic anaerobic streptococci. The patient's temperature was normal and remained so until the date of discharge, April 9, 1940, at which time her general condition was good.

Case 2 (see Fig. 3).—A woman, aged 32, was referred to the Hahnemann Hospital by Dr. H. Crowther.

She was admitted on January 28, 1940, complaining of abdominal pain and foul-smelling black vaginal discharge. She gave a history of having passed a small fetus two weeks earlier, following which the severe abdominal pain and discharge appeared. Physical examination revealed an extremely toxic patient with a temperature of 102.4 F.; pulse, 128; and respirations, 22. A routine blood count showed 3,850,000 red blood cells; 13.6 per cent, hemoglobin; and 9,050, white blood cells. A routine urinalysis was essentially negative. A provisional diagnosis of septic endometritis following spontaneous abortion was made. Sulfanilamide, 10 grains four times a day, was begun January 29. On January 30 the dose was increased to 20 grains every 3 hours, four doses daily. On the next day the patient became increasingly toxic and suffered from chills and her temperature rose to 103 F. The sulfanilamide level of blood rose to 8.2 mg. per hundred cubic centimeters. She continued to run a septic temperature, her

TABLE 1.—RESULTS IN CASES OF ACUTE PYOGENIC INFECTION GIVEN ULTRAVIOLET BLOOD IRRADIATION THERAPY AT THE HAHNEMANN HOSPITAL, PHILADELPHIA, FROM NOVEMBER 1, 1938 TO APRIL 1, 1941

described below; the average time of exposure in this work was ten seconds.

In irradiating blood ultraviolet wavelengths within the range, from 2,399 to 3,654 angstrom units were used. The intensities corresponding to the wavelengths used are shown in this table:

Å	mW/cm. ²	Å	mW/cm. ²
2,399	55,000	2,967	224,000
2,483	88,000	3,022	435,000
2,436	273,000	3,125-3,132	718,000
2,652	239,000	3,342	73,000
2,753	86,000	3,473	41,000
2,804	139,000	3,650-3,654	1,538,000
2,897	96,000		

The technic of administration consists, briefly then, in the withdrawal of a calculated amount of blood from a patient's vein, usually from an arm vein. It is then stirred gently with 2.5 per cent citrate, one part of citrate solution to five parts of blood. This citrated mixture is then poured through sterile gauze into a transfusion buret from which it is returned by the action of the synchronized electric transfusion pump of the hemo-irradiator to the patient's venous circulation.

Tabulation of Results

All cases of acute pyogenic infection given ultraviolet blood irradiation at Hahnemann Hospital, Philadelphia, up to April 1, 1941, are included in this report. The majority (63) of the cases reported received no form of chemotherapy; a minority (40) were admittedly chemotherapeutic failures.

The results of the use of this therapy in the treatment of cases of acute pyogenic infection can most readily be seen in tabular form in Table 1. This table is divided into three classifications according to the degree of toxic symptoms present at the time of the first irradiation—namely, as early, moderately advanced, or apparently moribund.

It will be observed from a study of Table 1 that 100 per cent of the early, and 98 per cent of the moderately advanced, cases recovered; moreover, 47 per cent of the apparently moribund cases recovered. Obviously, the earlier the treatment was applied the better were the results obtained.

In none of the cases treated has there been observed any harmful delayed effects, such as deleterious effects on the blood itself, as can be judged by the presence of normal red and white cell count and structure, as well as normal hemoglobin content in patients fol-

FIG. 4.

FIG. 5.

FIG. 4. CASE A.M.2, puerperal sepsis; pelvic peritonitis following cesarean section. Patient's condition became increasingly critical, despite sulfanilamide. Twenty-four to thirty-six hours following blood irradiation on the sixth day her high fever and toxic symptoms subsided. She was discharged on the sixteenth day of hospitalization, ten days after blood irradiation.

FIG. 5. CASE M.A.14, wound infection, pelvic thrombophlebitis following hysterectomy. Following hysterectomy this patient failed to run a normal postoperative course. Instead there developed a wound infection and a probable pelvic thrombophlebitis with increasingly severe toxic symptoms. On the fourth day following operation, blood irradiation therapy was instituted. Patient's toxic symptoms subsided within twenty-four hours; her wound infection rapidly disappeared. She convalesced uneventfully and was discharged in excellent condition thirteen days later.

gen tent was discontinued, and his distention was greatly lessened. The next day, December 11, dyspnea and cyanosis reappeared and blood irradiation therapy was repeated. The next morning the dyspnea and cyanosis disappeared. At this time the Wangenstein tube was prematurely removed and patient again became distended. A blood transfusion was given and the Wangenstein apparatus was reapplied on December 13. The patient became somewhat dyspneic and toxic symptoms began to reappear. Blood irradiation was given a third time. On the following day his general clinical condition was greatly improved. His abdomen was almost normally soft and peristalsis, which had disappeared the previous day, was re-established. From this point on he began to improve. It was possible for the first time to remove gradually all drainage tubes. On December 20 secondary suture of the abdominal wound was done, and the patient continued to convalesce uneventfully and was discharged from hospital in apparently fine condition on January 14, 1939.

In order to show a more detailed picture of the effect of ultraviolet blood irradiation therapy on septic temperatures, a series of graphs of peak temperatures selected from cases reported in Table 1 (see Figs. 4 to 7) are shown. These are typical of the whole group presented in this paper.

General Clinical Observations

During this work several rather outstanding clinical events were noted, and their relation to the known physiologic effects of ultraviolet

mentioned earlier in this paper have been correlated insofar as possible. These may best be summarized as follows:

1. The bactericidal effect has been noted throughout this work. A complete disappearance of the invading bacterial organism was found to occur except in cases of *Staphylococcus aureus* septicemia and in cases of subacute bacterial endocarditis.

2. The detoxification effect, to me, has been the most striking of all effects observed in cases of acute pyogenic infection following ultraviolet blood irradiation therapy. There occurs in these cases almost uniformly, twelve to seventy-two hours following this therapy, a pronounced subsidence of toxic symptoms, such as nausea, vomiting, delirium, fever, general malaise, rapid pulse, rapid respiration, etc. In this connection we have observed that there often occurs a marked fall in abnormally high temperatures. If, however, abscess formation is present or occurring, the abnormally high temperature will drop to a level slightly above normal; in such cases all toxic symptoms usually disappear and the elevated temperature drops to normal upon drainage of the abscess. In fact, we have found a disappearance of toxic symptoms in combination with a slightly elevated temperature following ultraviolet blood irradiation therapy to be pathognomonic of abscess formation.

3. Grossly discernible peripheral vasodila-

general condition became worse, and her sulfanilamide blood level dropped to 3.4 mg. per hundred cubic centimeters on February 4, on which day her red blood cells were 2,900,000; hemoglobin, 10.1 per cent; and white blood cells, 10,050. On February 6 and February 7 the patient's condition became extremely critical. Since sulfanilamide had failed, it was stopped at 10:00 a.m. on February 7.

Blood irradiation therapy was instituted at 2:00 p.m. on February 7. On the following day the patient appeared slightly improved generally. Her temperature fell to 99.4 F. On February 9 the temperature fell to 98 F. Her clinical condition, forty hours following blood irradiation, was strikingly improved at this time, and from this point on she convalesced uneventfully, leaving the hospital in apparently excellent health on February 18, 1940.

Case 3.—A girl, aged 18, was referred to the Hahnemann Hospital by Dr. D. A. Roman. A diagnosis of puerperal sepsis with probable staphylococemia and eclampsia was made.

The patient, who had been attending prenatal clinic because of increasing signs of pre-eclampsia, was admitted at term on April 3, 1940, complaining of nausea and severe headache during the twelve hours previous to admission. A physical examination revealed the following signs of impending pre-eclampsia: ankle and facial edema, blood pressure of 152/102, 4 plus albuminuria, and the presence of waxy granular casts in the urine. A routine blood examination showed 3,810,000 red blood cells, 12.7 per cent hemoglobin, and 11,300 white blood cells. Three hours after admission she began to have mild convulsions. Cesarean section was advised and performed immediately. Eclampsia continued the day following cesarean section. Two days after the operation, April 5, albuminuria was greatly decreased and the patient began to improve, her blood pressure falling steadily. Her temperature continued to fluctuate between 98 and 101.4 F. for the first fourteen days after cesarean section. In the meantime, on April 11 she had been transferred to the septic ward. Her general condition remained good and, despite an occasional temperature rise, she appeared to be improving in every respect until April 18 when her temperature rose to 102.6 F. at which time she complained of pain in her left leg. At this time a physical examination revealed no evidence of phlebitis. Her left leg pain continued and the temperature of 102 F. persisted. At this time, despite the absence of inflammatory signs, a diagnosis of phlebitis of the left leg was made on April 21. At this time the patient became moderately toxic, and mild convulsions appeared.

Blood irradiation therapy was instituted on April 22. The following day her temperature fell to 98.4 F. and then rose to 102.8 F., her condition being generally unchanged. One blood culture taken on April 22 proved negative; one

taken immediately before irradiation showed numerous colonies of *Staphylococcus albus*; one taken on April 24 was negative. On April 24 the patient was generally improved; her left leg pain and convulsions had disappeared completely, but her temperature remained elevated for the next three days. Blood irradiation therapy was repeated on April 27. In the next twenty-four hours the patient's condition improved markedly. Her temperature fell to 98.4 F., rose to 100.4 F., and fell immediately to 98.2 F. From this point on, she convalesced uneventfully and was discharged from the hospital in apparently excellent condition May 3, 1940.

Case 4.—A man, aged 52, was referred to the Hahnemann Hospital by Dr. L. Bower. A diagnosis of acute gangrenous appendix, generalized peritonitis, complicated by paralytic ileus and lobar pneumonia was made.

The patient was admitted on December 2, 1938, suffering from acute abdominal shock and giving a history of acute abdominal pain with nausea and vomiting twenty-four hours prior to admission. A physical examination revealed the probable presence of acute appendicitis. A routine urinalysis was negative. There were 20,250 leukocytes and 89 per cent neutrophils. He was operated upon on December 2 and a gangrenous appendix was removed. Appendectomy was followed by colostomy via lumen of the base of the appendix. A penrose drain was inserted, the peritoneum was closed, and the skin wound was packed with iodoform gauze.

The day following the operation he apparently developed right-sided atelectasis accompanied by dyspnea. His temperature rose to 102 F. On December 5 the patient was placed in an oxygen tent and later that evening an increasing abdominal distention was noticed and his temperature rose to 103 F. No peristalsis could be found and a diagnosis of acute widespread peritonitis was made. Prontosil was started, 20 cc. daily. On December 6 the peristalsis remained absent, and a blood transfusion was given. This was repeated December 8. The patient became more and more dyspneic and prontosil was stopped; his toxic symptoms increased; rales were heard over a widespread pulmonary area; and increasing leg and ankle edema became apparent. On December 9 he became markedly cyanotic, dyspnea became advanced, abdominal distention increased, he apparently was succumbing to an overwhelming toxemia, secondary to his peritonitis, paralytic ileus, and intrapulmonary complications.

Blood irradiation therapy was instituted on December 9. A few minutes afterward the patient's cyanosis had disappeared, his skin became quite pink, his dyspnea was markedly relieved, and he slept well throughout the night following blood irradiation therapy, the first sleep he had had since admission. The following day he appeared markedly improved in every respect. Peristalsis had reappeared, the oxy-

1. The bactericidal effect has been noted throughout this work. A complete disappearance of the invading bacterial organism was found to occur except in cases of *Staphylococcus aureus* septicemia and in cases of subacute bacterial endocarditis.

2. The detoxification effect, to me, has been the most striking of all effects observed in cases of acute pyogenic infection following ultraviolet blood irradiation therapy. There occurs in these cases almost uniformly, twelve to seventy-two hours following this therapy, a pronounced subsidence of toxic symptoms, such as nausea, vomiting, delirium, fever, general malaise, rapid pulse, rapid respiration, etc. In this connection we have observed that there often occurs a marked fall in abnormally high temperatures. If, however, abscess formation is present or occurring, the abnormally high temperature will drop to a level slightly above normal; in such cases all toxic symptoms usually disappear and the elevated temperature drops to normal upon drainage of the abscess. In fact, we have found a disappearance of toxic symptoms in combination with a slightly elevated temperature following ultraviolet blood irradiation therapy to be pathognomonic of abscess formation.

3. Grossly discernible peripheral vasodila-

Fig. 7.

Fig. 6. Case M. A. 38, acute suppurative appendicitis. Immediately following removal of a ruptured appendix, blood irradiation was used, and within twenty-four hours the patient's toxic symptoms began to subside. At the end of forty-eight hours his temperature dropped to normal, and he was discharged on the thirteenth day.

Fig. 7. Case M. A. 19, fever of undetermined origin following pyelotomy. The temperature dropped to normal and the toxic symptoms subsided twelve to twenty-four hours following ultraviolet blood irradiation therapy. The patient was discharged in good condition on the twentieth day of hospitalization.

tion has been observed in over 75 per cent of all individuals given ultraviolet blood irradiation therapy. This occurs within five to ten minutes after the irradiated blood has been returned to the venous circulation and persists in some individuals for more than thirty days.

4. Photosensitization and photodynamic effects have been carefully considered in this work, although there is neither time nor space here to present these studies. We have made a few fundamental observations regarding the combined use of chemotherapeutic agents, especially sulfanilamide derivatives, quinine, and iodides with ultraviolet blood irradiation therapy. These are, briefly: (a) Ultraviolet blood irradiation therapy can be given safely and with impunity following the administration of sulfanilamide derivatives, quinine, and iodides; however, those patients who have not received "sulfas" drugs prior to blood irradiation have a much shorter convalescent period. (b) Sulfanilamide, sulfapyridine, and iodides cannot be given safely within the first five days following ultraviolet blood irradiation therapy without risking a probable photosensitive reaction in the form of markedly increased toxemia, pulmonary edema, and renal shutdown. In the case of photodynamic action observed with sulfathiazole (given seven days after ultraviolet blood irradiation therapy) marked convulsions were seen; no serious effects have been seen with the administration of quinine in the first few days following this therapy.

9. A complete absence of deleterious effects has been noted in this work with acute pyogenic infections. Earlier this year I¹¹ reported that in individuals with initially normal red cell, white cell, and hemoglobin values there was observed to be little, if any, change one to thirty-six months following ultraviolet blood irradiation therapy carried out strictly in accordance with the technique and dosage described above. Similarly, we may add that in patients receiving blood irradiation for acute pyogenic infection and having abnormal hemoglobin, red cell, and white cell values before treatment all these disappear, changing

7. Secondary emanatory phenomena present difficult problems for careful analysis. At this time no statement can be made. Knott was able to fog a photosensitive film in a darkroom with the serum of blood irradiated according to the above-described technique.

8. General resistance, as may be expected in the light of the previously mentioned observations, was obviously increased.

5. The effects on various proteins have not yet been carefully studied by us, and we are unable to make any statement with regard to these at this time.

6. The ability of ultraviolet irradiated blood to absorb oxygen has been studied by me,¹⁰ and in this work it was found that in patients with abnormally low venous oxygen values following ultraviolet blood irradiation therapy there was a marked increase in the uptake of oxygen as shown by a definite rise toward normal of venous oxygen values.

to normal following hemo-irradiation. We have been unable to find delayed harmful effects of any nature in over 1,000 applications of the Knott technic of ultraviolet blood irradiation.

Up to the time of the writing of this paper, in the treatment of cases of acute pyogenic infection uncomplicated by septicemia we have never seen an infection progress to the point where a septicemia has ensued.

We have often seen, as have others, a complete failure of chemotherapeutic agents insofar as controlling the infection is concerned. Many of these cases have responded to ultraviolet blood irradiation therapy subsequent to chemotherapeutic failure. We have yet to witness a case in which ultraviolet blood irradiation therapy failed and chemotherapy succeeded.

The above clinical observations are in close agreement with those made by others working with the Knott technic of ultraviolet irradiation of blood—notably, Hancock,³³ Rebbeck,³⁹ and Barrett.⁴⁰

Summary

1. A method of irradiating human blood, that originally devised, and recently modified, by Knott, is described.

2. The amount of blood used (predetermined according to approximate body weight), the time of exposure (optimally ten to twelve seconds in the treatment of acute pyogenic infections), and the wavelengths and intensity of the spectral energy used form the basis for estimating and maintaining a relatively constant dosage.

3. A report of cases of acute pyogenic infection treated at Hahnemann Hospital over a period of twenty-nine months is given; the clinical response has been consistently excellent.

4. A rapid subsidence of toxic symptoms with subsequent recovery in all of the early cases, all of the moderately advanced cases, and in some of the apparently moribund cases of acute pyogenic infection was found to occur. Other beneficial physiologic effects—e.g., bactericidal effect, vasodilation, venous oxygen increase—were observed to occur following this therapy.

5. As yet, no case of acute pyogenic infection uncomplicated by septicemia, after receiving ultraviolet blood irradiation therapy according to the Knott technic, progressed to a septicemia.

Conclusion

1. The Knott technic of irradiating blood with ultraviolet must be considered, in view of the various physiologic effects it produces, a method of applying ultraviolet energy intravenously.

2. This method has been found to be valuable for controlling acute pyogenic infections rapidly and efficiently.

3. The technic described is essentially a hospital procedure, at present. It requires careful training in its use and when properly administered is without harmful aftereffects.

4. Experience with the Knott technic of irradiating blood has convinced us that it offers more to the patient suffering from acute pyogenic infection than any other therapy yet known.

This series included 1 case of fulminating erysipelas which had a really remarkable recovery. Immediately following ultraviolet blood irradiation therapy (i.e., twelve hours later) the rapidly advancing process had regressed markedly, the patient's toxic symptoms had disappeared, and the patient was discharged one week later in good condition.

6. Subacute bacterial endocarditis; in this group we had 10 cases and 10 deaths. All that pathology is a relief of toxemia. The focus of infection apparently cannot be reached, and we are working in this field feel that ultraviolet blood irradiation therapy does no good whatsoever insofar as final recovery is concerned.

7. Of the other 14 cases of septicemia treated there were 6 hemolytic streptococcal infections with 4 recoveries and 2 deaths. There were 5 cases of nonhemolytic streptococcal septicemia with 2 recoveries and 3 deaths. Also in this group were 3 colon bacillus septicemias with 2 recoveries and 1 death. One case of colon bacillus septicemia was accompanied by a Streptococcus hemolyticus septicemia but recovered. All of these cases that recovered were either treated by ultraviolet blood irradiation therapy alone or by ultraviolet blood irradiation therapy after chemotherapy had apparently failed to control the pathology. All of these patients with septicemia were in an advanced state before blood irradiation therapy was instituted.

8. We have found this therapy useful as a preoperative measure and believe our cases of major surgery convalesce better with than without its use.

A quick résumé of these cases of acute pyogenic infection shows 108 cases with 81 recoveries and 27 deaths; if we exclude subacute bacterial endocarditis, we find 81 recoveries out of 98 cases. Of these 98, 65 were moderately advanced when first seen and 33 were apparently moribund. Sixty-three of the moderately advanced cases recovered and 2 died; 15 of the apparently moribund cases (excluding subacute bacterial endocarditis) were not benefited by ultraviolet blood irradiation therapy and 18 recovered rather dramatically. Obviously, the earlier the cases were seen the better the results. Our results incidentally are in close accordance with those reported by Dr. Milley.

In conclusion, may I say it is my firm conviction that in the ultraviolet irradiation of autotransfused blood the medical profession has a therapy of marked value and, I believe, it will soon be recognized as an indispensable adjunct to the practice of good medicine and surgery.

Discussion

Dr. E. W. Rebeck, Pittsburg—Dr. Milley is to be congratulated for his fine presentation of this subject. I am sure we have all enjoyed his paper.

In the Shadyside Hospital, Pittsburg, we have been using this type of therapy since June, 1937. We have treated approximately 1,400 patients and given approximately 3,000 blood irradiations, chiefly in cases of a chronic type resistant to all other therapy. In the case of these patients we have made studies of red and white cell count and structure, hemoglobin content and formation, as well as of routine blood chemistry, urinalyses, and often kidney function; we have seen no evidence of any harmful effects as yet following ultraviolet blood irradiation therapy.

In the acute pyogenic infection field we might list as of special interest several main groups: 1. Nineteen cases of acute appendicitis complicated by abscess formation with 15 recoveries and 4 deaths; one of the latter had a colon bacillus septicemia and multiple liver abscesses on admission and was obviously moribund.

2. Acute generalized peritonitis secondary to acute appendicitis with perforation; in this group are 17 cases with 11 recoveries and 6 deaths. Of these 6 deaths, 4 were hopelessly moribund by the time therapy was instituted. The 2 remaining nonrecoveries were apparently uninfluenced by the ultraviolet blood irradiation therapy.

3. Puerperal sepsis, including acute septic endometritis with or without acute parametritis and pelvic abscesses; in this class we are able to report 20 recoveries and 1 death.

4. Postabdominal sepsis; in this group we had 14 cases and 14 recoveries. It has been our day following irradiation. Despite this radical change from regular medical procedure, these patients have all done remarkably well and made uncomplicated recoveries.

5. Acute cellulitis, lymphangitis, lymphadenitis; here we have had 13 cases and 13 recoveries.

THE PRACTICAL MANAGEMENT OF ECZEMA IN INFANTS AND CHILDREN

EARL D. OSBORNE, M.D., JAMES W. JORDON, M.D., and JOSEPH J. HALLITT, M.D.,
Buffalo, New York

IN 1938 we published our impressions regarding the importance of contact and environmental allergens as a cause of eczema in infants and children.¹ Our observations along this line extended back to 1926. We called attention to the inadequacies of scratch, intradermal, and patch tests and to elimination diets in the management of these cases. We concluded that dietary regulations are of minor importance in children past 3 years of age, are slightly more important in children from 1 to 3, and are of importance in from 15 to 20 per cent of babies under 1 year of age. For the purposes of this paper we have reviewed the records of 124 patients who were carefully examined and treated during the years 1938 to 1940. Our recent observations have more than confirmed our original views. We are convinced that hypersensitivity to foods as a cause of eczema in infants is a minor factor certainly in not over 10 to 15 per cent of cases, and in older children is of considerably less importance.

Erroneous conclusions are easily drawn in the treatment of eczema in infants and children. Observers are apt to forget that approximately 50 per cent of all infants and children with eczema markedly improve or are entirely cured when hospitalized in the ordinary children's ward, devoid of wool and feathers, and put on normal diets. Recently, one observer² reported on the effectiveness of soybean food in the treatment of this form of eczema. Detailed scrutiny of this paper, however, reveals the fact that the children were hospitalized and all contact and environmental allergens were removed. He concluded that 50 to 60 per cent of infants and children with eczema are benefited by soybean foods. I submit that under the conditions of the treatment the percentage benefited would have been the same if he had not fed soybean food but had put the children on a normal house diet. Just recently, another observer reported improvement in approximately 50 per cent of cases on the feeding of lard in cases hospitalized. These con-

clusions are entirely unjustified. Another observation that should not be forgotten is that most children hypersensitive to some particular food show symptoms of intestinal disturbance when that particular food is ingested. Furthermore, hypersensitivity to ingested foods is usually, but not always, manifested in the skin by an urticarious reaction. It is always necessary to determine whether an eczema is secondary to an urticarial reaction in the skin or is a pure dermatitis from the onset. Eczematous response to ingested foods is the exception and not the rule.

Scratch and Intradermal Tests

Our opinion regarding the efficacy of scratch and intradermal tests is no different today than it was three years ago. In our opinion they are of exceedingly limited value. We have never been able to correlate the results of our tests or those of others with the actual clinical facts brought out by history and subsequent course. To rationalize scratch and intradermal tests to food proteins, one must assume that the ingested protein is absorbed at least partially unchanged and reaches the cutaneous cells in relatively the same form in which it exists in the material used for testing. Although this has been shown to be true of certain foods, particularly egg albumen, it demands a considerable stretch of the imagination to assume that this occurs in every instance in which a positive reaction to a scratch or an intradermal test exists. It is significant that many dermatologists and allergists have recently called attention to the shortcomings of scratch, intradermal, and patch tests.³⁻⁹

Patch Tests

We are also of the opinion that patch tests are of limited value in the practical management of eczema in infants and children. Actual clinical trial is the only sure test. Patch tests on infants and young children are of value when two, three, or four strongly suspected contact substances can be applied next to an entirely normal area of skin adjacent to an eczematous area. In this way clear-cut reactions can sometimes be obtained. With infants it is frequently im-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Department of Dermatology and Syphilology, University of Buffalo, School of Medicine.

possible to do a series of routine patch tests. The eczema is apt to be too generalized and the baby's skin too irritable to allow performance of satisfactory tests. Mild eczema may be made more severe, and there is an added danger of causing further hypersensitivity. Also, patch tests in general give negative results when the subject is atopic. We believe that patch tests are of more value in following up leads obtained by careful study of the history and of environmental and contact factors. Usually, it is best to postpone patch tests until the acute stage of the eczema has subsided.

The efficacy of patch tests on infants and children with protein substances is undecided and needs further investigation. Most authorities agree that these tests are generally negative. However, Peck and Salomon² and Peck³ have reported relatively high percentages of positive reactions to patch tests with protein substances in eczema of infants and children. While we have occasionally seen positive patch tests with protein substance in both infants and children, these positive tests have usually been delayed and have never been accompanied with vesiculation. We have frequently observed the development of a patch of erythematous squamous eczema in an infant or child at the exact site of contact with wool or feathers. Usually, this original patch has been on the cheeks, neck, elbow, wrists, or the popliteal area and, subsequently, atopic dermatitis has developed on other areas as a result of the dissemination of the offending allergen in the blood stream. A patch test on the back or arm of an infant with a protein substance does not approximate the actual clinical condition present in the production of a localized patch of eczema from contact with such a substance. It is our impression that moisture and friction are necessary and, of course, minute abrasion of the skin resulting from the friction. Before we can state that a patch test with a protein substance is negative, we must follow the first rule of patch testing—namely, approximate the condition present clinically. This is most easily done in practice by actual clinical trial, such as having the child wear a wool glove or a fuzzy sweater or coat.

Summarizing our impressions regarding patch tests in infants and children, we believe that they are of limited value and that actual clinical trial is the only sure test.

Method of Procedure

1. Investigation of (a) The family history of allergy. This is of slight importance in the individual case. (b) A history of definite reactions to specific foods. This information is recorded for future use. (c) The age at onset. We have never seen an infant under 10 days of age with eczema due to hypersensitivity. (d) The exact location of the first area of eczema and the site of subsequent attacks, especially the first area, to show evidences of exacerbations. (e) Contact substances, including soaps, laundry chemicals, medicated oils, powders, wool, silk, feathers, dogs, cats, insect sprays, kapok, the mother's and father's cosmetics, hand lotions, and toys. (f) Previous treatment, especially by local application.

2. Examination of the patient, with particular note of the area of onset; of sharply limited free areas, such as the nose, the upper lip, and the chin; and of sharp limitations of the ankles, wrists, and cheeks. Evidence of dissemination of the offending allergen through the blood stream and an estimate of the degree and extent of sensitization are extremely important.

3. Outline of treatment to the parents. This is often difficult because many intelligent, as well as ignorant, parents refuse to believe in the importance of external contact and environmental allergens. It is essential to convince them that the first procedure is the elimination of these factors, which requires from four to eight weeks of observation. A list of the common contact and environmental allergens is given to them with a detailed explanation that an infant must be kept in its crib or suspended in a canvas hammock and isolated from all contacts and environmental allergens. We insist on the removal of all wool and silk from the room, including carpets, rugs, and blankets, followed by frequent use of a vacuum cleaner. In cases of severe eczema we have insisted on hospitalization, and in a number of instances the use of an air-conditioned room has been of great assistance. However, in our experience the ordinary children's ward, free of all the common contacts, has proved adequate for a fair trial with all except highly sensitized children. One of the main benefits of the air-conditioned room is the maintenance of an absolutely even temperature and humidity. As is well

known, a high temperature frequently leads to excessive scratching, and when the humidity is low the dryness of the skin tends to induce excoriation. We emphasize again that from four to eight weeks is essential for a proper test in many cases. Hospitalization for such a period is impossible for many families unless free ward beds are at the disposal of the physician. Our best results have come in cases in which such accommodations have been available. When one is once convinced of the importance of contact and environmental allergens in a given case, any subsequent exacerbation should be carefully investigated, preferably by personal inspection of the environment.

4. Subsequent office visits at one- or two-week intervals. Answers to well-directed, searching questions relative to all common eczema-producing contact and environmental substances should be elicited.

5. Search for the specific cause of the eczema when the child is free of eruption. This can be done by patch tests, which are not always conclusive and, in our opinion, not as valuable as actual clinical trial.

6. Re-examination of the child and of the environment at the first sign of a recurrence.

7. Other methods of investigation, including elimination diets.

In carrying out this program, a searching detailed history is absolutely essential. The development of a high degree of skill as a detective is even more important, and its application more highly specialized, than an eczema in adults. Success or failure frequently hinges on a personal examination of every possible contact substance in the environment of the child. Immediate verbal answers by the parents or by nursemaids are notoriously unreliable, and experience has taught us that our results are in direct proportion to the time and effort extended in investigating the environment.

The following is a list of reasons for failure in the management of eczema of infants and children: (1) ignorance of the parents; (2) poverty of the parents; (3) indifference in the carrying out of directions; (4) lack of careful history, especially regarding point of onset; (5) lack of careful examination; (6) too much reliance on scratching, intradermal, and patch tests; (7) lack of time and patience in explaining problems to parents; (8) lack of detective instinct on part of physician; (9) lack of careful follow-up and examination of environment; and (10) use of irritating applications.

The most common contact and environmental allergens of importance in eczema of infants and children are:

(A) *Water soluble protein allergens*—wool, silk, feathers, and other animal epidermal products (in babies with thin stratum corneum, local contact dermatitis is possible. Allergens may be absorbed through inflamed or normal skin or by inhalation. Walls of blood vessels in upper corium are sites of primary shock tissue).

(B) *Chemical substances*—soaps, laundry chemicals, tanning chemicals, dyes, lacquered objects, medications, fish oil, oils from fruits and vegetables, cosmetics, weeds, and plants. (Epidermal cells are sites of shock tissue.)

Local Treatment

In most cases of eczema of infants and children, and certainly in all acute cases, only soothing treatment is indicated. In acute vesicular and pustular eczema, wet dressings of Burow's solution, saturated solution of boric acid, or potassium permanganate—1 to 4,000 dilution—are indicated. They should be applied on the most severe areas, six to eight hours per day. Soothing ointments and lotions should then be applied. Five per cent boric acid in plain petrolatum is satisfactory, as is also plain calamine lotion, calamine liniment, and emulsions of olive oil and lime water. Crude coal tar beginning with a 2-per cent strength is extremely valuable as a local application in eczema of infants and children. This is true in not only subacute and chronic cases, but in most acute cases. For the first three or four days the crude coal tar ointment should be applied only to limited areas in order to determine whether there is any hypersensitivity to this product. It may be applied twice a day and, therefore, kept on during the entire twenty-four hours or, as is our custom, it may usually be prescribed for use at night and a soothing liniment for use during the day. It should always be remembered that crude coal tar contains a photosensitizing fraction and that any child receiving this treatment should not be exposed to sunlight unless the crude coal tar is completely removed from the skin. We prefer a washed, distilled crude coal tar put up in a vanishing cream base, containing about 10 per cent of zinc oxide. It is always well to start with a strength of 2 per cent and later increase up to 5 per cent if well tolerated. Small fractional doses of x-ray are sometimes of extreme value in the management of severe cases. Two to

four treatments, not exceeding 50 to 75 rat units, seem to be effective. It should be emphasized, however, that reliance should not be placed on x-ray therapy for cure of the condition.

Soap and Laundry Chemical Substitutes

As we have emphasized previously, we believe that many cases of eczema are due to specific hypersensitivity to certain ingredients in these substances. It is also generally agreed that soaps and laundry chemicals act as irritants in any case of eczema and should be discontinued. As substitutes for soap we recommend either a sulfonated oil or a 5 per cent lauryl sulfoacetate in urea, both of which are now available on the market. As a substitute for laundry soap and other laundry cleaners, we recommend the use of a powder containing aryl sulfonate or some other related substance.

Summary

Investigation of contact and environmental allergens in eczema of infants and children brings a high percentage of satisfactory results.

Routine scratch and intradermal tests are entirely inadequate, unreliable, and misleading in investigation of eczema of infants and children. Routine patch tests of infants and children are not usually satisfactory; actual

clinical trial is more important. Patch tests with protein substances generally produce negative results in infants and children. Widely used, they do not conform to the first rule of patch testing—namely, that actual clinical conditions must be duplicated.

Dietary measures are of secondary importance in the practical management of eczema in infants and children. In our opinion, hypersensitivity to foods does not occur in more than 10 to 15 per cent of cases of eczema in infants and much less in eczema of children. The more common contact and environmental allergens are listed, and the principle reasons for failure in the management of these cases are given.

Local treatment is of importance and should generally be of a soothing nature, including the proper use of crude coal tar.

PREPARE FOR EMERGENCIES

The New York Academy of Medicine and the Medical Society of the County of New York are cooperating with the Chief of Emergency Medical Service for Manhattan in making available to New York physicians a series of four lectures and demonstrations on Emergency Medical Service. The series is based on the course in Advanced First Aid as prepared by the American Red Cross and the National Office of Civilian Defense. The four lectures and demonstrations were given at The Academy of Medicine on December 22 and 29. The next two will be on January 5 and 12 at 4:00 p.m.

On December 22 "Organization of Emergency Medical Service in New York" was discussed by Dr. George Baehr, director, Medical Division, National Office of Civilian Defense; "The Principles and Management of First Aid," was discussed by Captain Chas. D. Sully, C.M.H., director, First Aid Instruction, New York

Chapter, American Red Cross. On December 29 "Emergency Care and Transportation of Fractures" was discussed by Dr. Robert H. Kennedy, director of surgery, Beekman Hospital; chairman, National Fracture Committee, American College of Surgeons. A movie on "Emergency Splinting," produced under auspices of the Regional Fracture Committee, American College of Surgeons, was shown.

On January 5 Dr. Frederick W. Bancroft, president, New York Surgical Society, will talk on "Emergency Care of Abdominal Injuries, Head and Chest Injuries, and Burns," and on January 12 "Emergency Care of Wounds, Hemorrhage, Shock" will be discussed by Dr. Lawrence M. Thompson, chief, First Aid Division, American Red Cross.

Dr. Condict W. Cutler, Jr., is chief of the Emergency Medical Service for the Borough of Manhattan.

THE ADEQUATE TREATMENT OF PROSTATIC DISEASE

With Special Reference to Pathology

ROY B. HENLINE, M.D., New York City

THE surgical treatment of prostatic disease has reached a high degree of success in the hands of many urologists. By either the suprapubic, perineal, or transurethral methods, the prostatic obstruction may be removed in most instances with a low mortality and morbidity. The particular method used for removal of this obstructing tissue has depended to a large degree on the choice of the surgeon, who considers only his training and ability to relieve the obstruction. In some instances he has overlooked the underlying pathology and has not selected the operation that would give the patient complete and permanent relief from his prostatic disease. In other words, the surgical procedure employed should not depend on the surgeon's skill in one method but upon the pathologic process involved in the prostate.

It is essential that renal damage, infection, hemorrhage, and retention of urine be considered in all patients with prostatic disease. These have been thoroughly discussed in the literature. One finds statistics with low mortality figures for each type of surgical approach to the prostate. We are aware that these low mortality statistics are the result of proper preparation of the patient by a surgeon who is highly skilled in the surgical approach he advocates. Given the same patients, with a surgeon skilled in a different surgical approach to the prostate, it is likely that similar mortality statistics would result.

Etiology and Pathology

The cause, or at least the prevention, of hyperplasia of the prostate in advancing years has not been definitely determined. The exact locality and origin of the early stages of prostatic hyperplasia have been the subject of discussion for many years. All have agreed that the new growth is first seen near the urethra under the mucosa. Tandler

and Zukerkandl, among others, believed that prostatic hyperplasia developed from the short prostatic glands, which only extend a short distance beneath the mucosa in the prostatic urethra. This is the locality where hyperplastic changes are first seen in the prostate. Deming and Wolf, in studying 210 prostates, have recently shown that hyperplasia is first seen as a fibromuscular mass in the muscular wall of the prostatic urethra and suggest that this mass may correspond to uterine myomas, since they have a common embryologic anlage. These fibromuscular masses lie parallel to the muscular fibers of the urethra between the prostatic ducts and stimulate epithelial hyperplasia from these ducts of the prostatic glands. They state that this hyperplasia is not an enlargement of existing prostatic glands but, although similar in structure, is composed of newly formed glandular elements originating from the ducts of the functioning prostatic glands. This explains its locality surrounding the prostatic urethra from which the growth extends to compress the functioning prostatic glands toward the capsule and, eventually, also causes urinary retention. As this hyperplasia increases in size, some of the ducts from the functioning prostatic glands are compressed, and the prostatic secretion from these glands cannot escape into the urethra. If these glands are infected, a walled-off focus of infection may result in these remnants of the prostate gland. This condition often exists and may be readily demonstrated when hyperplasia coexists with prostatic calculi. The hyperplasia compresses the normal prostatic ducts, and the endogenous calculi, often with infection, remain in the prostatic glands as they are compressed toward the capsule of the prostate. In other words, the hyperplasia separates the compressed prostatic glands from their normal connection with the prostatic urethra.

This hyperplasia of the prostate usually occurs in the muscular layer under the urethra to compress the lateral and median prostatic lobes but may also develop in the subcervical or subtrigonal glands. It never occurs in the posterior lobe of the prostate, nor does it originate in the functioning glands of the lateral or median prostatic lobes. How-

Read before the North Carolina Urological Association, Greensboro, North Carolina, October 13-14, 1940. Also read before the Section of Genitourinary Surgery of The New York Academy of Medicine, New York City, January 15, 1941, at the twentieth anniversary of the founding of the Department of Urology, James Buchanan Brady Foundation of the New York Hospital, Cornell Medical School.

four treatments, not exceeding 50 to 75 rat units, seem to be effective. It should be emphasized, however, that reliance should not be placed on x-ray therapy for cure of the condition.

Soap and Laundry Chemical Substitutes

As we have emphasized previously, we believe that many cases of eczema are due to specific hypersensitivity to certain ingredients in these substances. It is also generally agreed that soaps and laundry chemicals act as irritants in any case of eczema and should be discontinued. As substitutes for soap we recommend either a sulfonated oil or a 5 per cent lauryl sulfoacetate in urea, both of which are now available on the market. As a substitute for laundry soap and other laundry cleaners, we recommend the use of a powder containing aryl sulfonate or some other related substance.

Summary

Investigation of contact and environmental allergens in eczema of infants and children brings a high percentage of satisfactory results.

Routine scratch and intradermal tests are entirely inadequate, unreliable, and misleading in investigation of eczema of infants and children. Routine patch tests of infants and children are not usually satisfactory; actual

clinical trial is more important. Patch tests with protein substances generally produce negative results in infants and children. Widely used, they do not conform to the first rule of patch testing—namely, that actual clinical conditions must be duplicated.

Dietary measures are of secondary importance in the practical management of eczema in infants and children. In our opinion, hypersensitivity to foods does not occur in more than 10 to 15 per cent of cases of eczema in infants and much less in eczema of children. The more common contact and environmental allergens are listed, and the principle reasons for failure in the management of these cases are given.

Local treatment is of importance and should generally be of a soothing nature, including the proper use of crude coal tar.

PREPARE FOR EMERGENCIES

The New York Academy of Medicine and the Medical Society of the County of New York are cooperating with the Chief of Emergency Medical Service for Manhattan in making available to New York physicians a series of four lectures and demonstrations on Emergency Medical Service. The series is based on the course in Advanced First Aid as prepared by the American Red Cross and the National Office of Civilian Defense. The four lectures and demonstrations were given at The Academy of Medicine on December 22 and 29. The next two will be on January 5 and 12 at 4:00 p.m.

On December 22 "Organization of Emergency Medical Service in New York" was discussed by Dr. George Baehr, director, Medical Division, National Office of Civilian Defense; "The Principles and Management of First Aid," was discussed by Captain Chas. D. Scully, C.M.H., director, First Aid Instruction, New York

Chapter, American Red Cross. On December 29 "Emergency Care and Transportation of Fractures" was discussed by Dr. Robert H. Kennedy, director of surgery, Beekman Hospital; chairman, National Fracture Committee, American College of Surgeons. A movie on "Emergency Splinting," produced under auspices of the Regional Fracture Committee, American College of Surgeons, was shown.

On January 5 Dr. Frederick W. Bancroft, president, New York Surgical Society, will talk on "Emergency Care of Abdominal Injuries, Head and Chest Injuries, and Burns," and on January 12 "Emergency Care of Wounds, Hemorrhage, Shock" will be discussed by Dr. Lawrence M. Thompson, chief, First Aid Division, American Red Cross.

Dr. Condict W. Cutler, Jr., is chief of the Emergency Medical Service for the Borough of Manhattan.

pated in the prostate by rectal examination, a perineal exposure with complete removal of the prostate offers the only hope of cure if it proves to be an early carcinoma of the prostate. Since this area can be reached only by the perineal approach, the patient deserves to be operated upon by the method that offers him an opportunity to be cured.

When we consider that one out of every 5 to 7 patients past 50 years of age has a carcinoma of the prostate, are we not justified in removing the posterior lobe of the prostate, in a suspicious case, together with the obstructing portion of the gland? All other methods of treating prostatic carcinoma are rarely curative and only offer relief from symptoms. It is our custom to expose the prostate by perineum when a suspicious nodule has been palpated in the prostate. A small section of this area is removed and a frozen section is made at once. If carcinoma is discovered, a radical perineal prostatectomy is performed, including the entire prostatic urethra and seminal vesicles. If the biopsy proves benign, either a conservative prostatectomy is performed, if indicated, or the perineum is closed. Exposure of the prostate by perineum with a biopsy is far superior to repeated attempts to obtain a specimen with a needle through the perineum. A negative report from a needle biopsy proves nothing, since the small involved area may easily be missed. In a recent patient the small perineal biopsy removed the entire malignant area, and careful microscopic examination of the rest of the prostate and seminal vesicles failed to reveal any malignancy.

Since malignancy of the prostate is so common and until such time arrives when our treatment of prostatic carcinoma is more satisfactory in curing these patients and preventing the subsequent suffering, it may not be unreasonable to consider the advisability of removing the posterior prostatic lobe and capsule when surgery must be instituted anyway for obstruction. Although I do not recommend this procedure routinely, statistics may force us to consider it in the future if we

wish to offer our patients the best future outlook for continued health. I am opposed to the pessimism frequently spoken regarding carcinoma of the prostate. For a urologist to palpate a suspicious hard nodule in a prostate and wait to see what happens is a violation of the trust placed in him. These are the only patients we hope to cure of this disease and, unfortunately, most of them have no urinary symptoms! For the greater number of patients with prostatic carcinoma where extension has occurred, transurethral resection offers relief from urinary retention, and deep x-ray therapy often relieves the pain from metastases.

Conclusion

In conclusion, may I repeat that only the prostatic hyperplasia or fibrosis may be removed by suprapubic "prostatectomy" or by transurethral resection. To remove the prostate gland, a perineal exposure is necessary. Only by perineum can the posterior lobe (the site of 75 per cent of malignancies of the prostate) be removed together with the compressed remnants of the functioning prostatic glands. Only by maintaining a clear conception of the various pathologic lesions that may involve the prostate and only after proper study should we decide on the rational surgical procedure in each case. To treat all surgical prostatic disease by one method is not sound from a pathologic point of view. We, as surgeons, are rightly to be considered inadequate if, through lack of preliminary investigation, study, and understanding of the pathology present, we fail to approach our problem by that method which is particularly fitted to give adequate permanent relief.

"There are some people—and I am one of them—who think that the most practical and important thing about a man is still his view of the universe. We think that for a landlady considering a lodger it is important to know his

income but still more important to know his philosophy. We think that for a general about to fight an enemy it is important to know the enemy's numbers but still more important to know the enemy's philosophy."—K. G. Chesterton

ever, malignancy of the prostate is said to originate in the posterior lobe in about 75 per cent of cases. Recent statistics by Moore and Rich draw our attention to the fact that between 14 and 16 per cent of all men over 50 years of age have a carcinoma of the prostate. Although these percentages seem rather large, carcinoma of the prostate is either becoming more common or is being recognized more frequently. In treating prostatic disease, one cannot overlook these findings without giving serious thought to their rational treatment. It has been suggested that since the average life expectancy of men has been increased one should expect to find prostatic malignancy more frequently.

Diagnosis

Every means at our disposal should be employed to determine the exact nature and extent of prostatic disease before the type of surgical procedure to be employed is decided upon. The presence of frequent urination, with the finding of residual urine in the bladder and an enlarged prostate by rectal examination, is insufficient evidence to suggest a particular type of surgical procedure to be employed. The exact location and extent of the obstruction should be established. The presence of prostatic infection, fibrosis, and calculi should be determined. The presence of a hard nodule in the prostate on rectal palpation arouses a suspicion of malignancy. Cystoscopy is often helpful but, in some patients, is inadvisable or impossible of performance. An aerogram and cystourethrogram in a semilateral position is a distinct aid in diagnosis and in most instances can be performed with little discomfort to the patient. It is our impression that a more exact impression of the size, location, and extent of the obstructing tissue may often be obtained by cystourethrograms.

Treatment

It has been so common for all of us to refer to the various types of prostatic surgery as "removal of the prostate" that many surgeons forget that the prostate is rarely actually removed. Only the hyperplastic tissue or so-called adenoma is removed, and the functioning prostatic glands or their remnants still remain firmly attached to the capsule. Removal of this hyperplastic tissue is frequently all that is required to establish adequate bladder drainage, and the remaining uninvolved prostatic tissue may reasonably be left behind. It is not uncommon, how-

ever, for the remaining prostatic glands to be the seat of a pathologic process that also requires removal to cure the patient. Among the most common causes requiring total extirpation of the prostate in some patients are prostatic calculi, marked infection with fibrosis, and early malignancy.

Transurethral removal of obstructing hyperplasia of the prostate is a rational procedure and has assumed an important place in prostatic surgery. With proper selection of cases and a skilled surgeon, excellent results can be obtained. Opinions vary as to the size of the prostate best treated by transurethral surgery. However, with a surgeon properly skilled in this procedure, relatively large hyperplasias may be adequately removed in this manner. Some surgeons prefer to remove large intravesical prostatic hyperplasias suprapubically, and similar results may be obtained in these cases by either method.

When it becomes desirable to remove the remnants of the functioning prostatic glands because of infection, calculi, or a hard nodule in the prostate which arouses one's suspicion of malignancy, it is essential to approach the prostate by the perineum. Only through the perineum can these prostatic remnants be removed. Neither by transurethral nor suprapubic approach is it possible to remove either these prostatic remnants or the posterior lobe of the prostate. The posterior lobe and false prostatic capsule are separated from the hyperplasia of the prostate by a line of cleavage which permits the hyperplastic tissue to be cleanly "shelled out" suprapubically. These remnants of the prostate, in which it is estimated that 75 per cent of carcinoma develops (posterior lobe), must, of necessity, be left behind in either a suprapubic enucleation or a transurethral resection.

In some patients who have had a so-called prostatectomy, a postoperative morbidity persists with infected urine and frequent urination. These symptoms are distressing to the surgeon and the patient. Although many of these are caused by pathology of the upper part of the urinary tract or infected bladder diverticuli, a certain percentage of them result from infection in the remnants of the prostatic tissue or the seminal vesicles. If this infection had been determined before operation, this postoperative morbidity could have been prevented by removal of the prostatic capsule and prostatic remnants by perineum together with the hyperplasia.

When a suspiciously hard nodule is pal-

effects on the blood pressure and skin level of anesthesia.

Despite important advantages, certain theoretic disadvantages are present which weigh heavily in making the decision to use this fractional technic for the first time. These doubts relate to the increased possibility of nerve root injury, to infection, and to meningeal irritation from the prolonged presence of the spinal needle. Further, the question of the effect on the cord and meninges of repeated injections of drugs arises. It is known, of course, that all anesthetic drugs studied thus far (and physiologic saline²) produce irritation.

At the present time our minor complications have increased with the use of this technic. The site of the lumbar tap in 1 instance on the sixth day developed an abscess that had to be opened. There were no meningeal symptoms accompanying this complication. Furthermore, our incidence of headache has increased markedly to 25 per cent from approximately 15 per cent previously. One case of severe backache throughout the first ten postoperative days occurred. Apparently, with the use of this technic a few minor complications have been substituted for major ones. Yet, on balance, we see no reason to question Lemmon's suggestion that operating table pads in the future should be manufactured to enclose a space for accommodating a spinal needle.

Technic

Our technic for fractional dosage spinal anesthesia at first followed that published by Lemmon. Later, several adjustments were made in the interest of simplicity. From our experience we now feel that anyone familiar with spinal anesthesia can undertake this technic with a minimum of special equipment.

The specially constructed mattress, with a cut-out area in the region coming adjacent to the lumbar spine of the patient for the accommodation of the protruding spinal needle, was probably of fundamental importance in the conception of this technic. Yet, early experience taught us that this clumsy equipment was unnecessary. First, we substituted two sets of three folded sheets placed under the lumbar region in such a way as to form a slot for the protruding needle.

Later, it was found that even the lower groups of sheets was unnecessary except for the heaviest patient. The folded sheets placed just headward to the needle produced an elevation of about 2 inches for protecting

the protruding spinal needle. By utilizing the depth of the longitudinal midline lumbar furrow and a reasonably short needle, this limited extra elevation was adequate. Increased elevation can readily be attained if necessary.

This arrangement, in certain special situations at least, produced considerable improvement. The patient at times actually liked the feeling of support under his back. (Occasionally, patients insist on having something placed "in the small of the back" regardless of the type of anesthesia.) The operating room staff found it unnecessary to move a cumbersome mattress from room to room for these cases. The surgeons disliked the high elevation produced by the thick mattress. This extra elevation, furthermore, made it necessary to obtain especially made shoulder braces to hold the patient in the Trendelenberg position. In our experience, the older ones would no longer fit over the increased mattress thickness. This complication was not anticipated and proved embarrassing in the first case. Further, in making cholangiograms during surgery, it was feared that the thick mattress and rubber covering would interfere with the clarity of the pictures; the folded sheets did not.

From the first we have used a 5 per cent solution of procaine rather than the 10 per cent suggested by Lemmon. We soon found that this solution, together with a technic using a low spinal tap and minimal diffusion, necessitated the use of larger amounts of the anesthetic drug than we had anticipated. The 500 mg. ampule of procaine crystals was then used rather than the smaller-sized ampules. Five hundred milligrams were dissolved with 5 cc. of spinal fluid, and to this was added 5 cc. of either physiologic saline or sterile distilled water. When a second ampule of procaine was necessary, the drug was dissolved in physiologic saline or sterile distilled water without the addition of spinal fluid.

Three features of this technic were emphasized in the original description. They were: (1) the mattress, (2) the tubing connection, and (3) the special spinal needle. We have already shown how subsequent experience proved the special mattress, though at times desirable, to be unnecessary. We found further that the connection between the needle and syringe can be improvised provided high-grade, nondistensible, small bore rubber tubing is used and provided the internal volume is accurately measured. A Luer-loc connection to the needle end of this tubing is necessary. A simple rubber-to-glass

OBSERVATIONS ON CONTINUOUS SPINAL ANESTHESIA

G. EDGAR BURFORD, M.D., and WILLIAM H. GALVIN, M.D., New York City

AN ORIGINAL contribution by W. T. Lemmon,¹ of Philadelphia, has applied a renewed stimulus to the search for improved spinal anesthesia.

Lemmon described a technic for making repeated injections of the anesthetic drug into the subarachnoid space at any time during the operation. The technic utilized a special needle, tubing connection, and mattress. The effect of this communication was to change for the better the thoughts of many surgeons and anesthetists concerning the reliability, the safety, and the future development of spinal anesthesia.

The reliability of spinal anesthesia has been made almost absolute by the use of this method. The need of supplementary anesthesia has practically vanished.

The safety of spinal anesthesia has been increased almost in proportion to the reliability. The possibility of an initial large injection proving toxic, either by reason of rapid absorption into the blood or extensive cephalad diffusion with concurrent respiratory and vasomotor paralysis, is in a large measure removed. The frequent small additions of the drug allow a gradual detoxification. Further, for the first time, the headward diffusion of the anesthetic to the level necessary to produce adequate anesthesia can be reasonably accurately controlled. This is true despite all the material that has previously been written about attempts to control the level of spinal anesthesia. Besides this, provided vasopressor drugs have not been used, the progress of cephalad diffusion may also be followed, to some extent, by the effect on the blood pressure.

The future development of spinal anesthesia has been affected to an equal degree. The attention of the chemist and pharmacologist will be shifted from the development of long-acting anesthetic drugs to shorter-acting ones. The short-acting drug, of course, increases the safety of spinal anesthesia with this technic by rapidly losing effectiveness should too high a level of anesthesia become established. For the present, procaine again becomes the drug of choice.

Because of the ability to repeat the dosage up to the desired effect, the clinical anesthetist using this technic can cease to worry about the angle at which the patient lies on the table. The emphasis on hyperbaric, hypobaric, and isobaric solutions, which have so frequently been praised or blamed as the controlling factor in establishing the level of anesthesia, may soon be forgotten.

In addition, answers are already being provided the clinical anesthetist to many unsolved problems in spinal anesthesia. These answers come from the most reliable source—the human patient. For instance, the problem of the harmful effect, if any, produced by anesthetic drugs through direct absorption after subarachnoid injection can be studied and compared to the effect of the paralyzing action on respiratory and vasomotor nerves. To anticipate in this connection, our results seem to demonstrate that absorption toxicity is slight and probably far less important than previously believed. Furthermore, positive demonstration of the effect of cephalad diffusion in man on the blood pressure can be given. Again to anticipate, the blood pressure falls when a sufficient quantity of an anesthetic drug is injected into the subarachnoid space to involve effectively the high thoracic levels of the cord.

While increased safety and reliability are the two major improvements resulting from this fractional technic, they do not represent all the advantages. This method appeals to surgeons. Many of them who previously studiously avoided spinal anesthesia because of its major defects readily adopt this method. The anesthesiologist is thus aided, in certain circumstances, in selecting what he considers the best anesthetic for the patient.

Another advantage lies in the fact that the patient can be prepared for anesthesia and operation a reasonable length of time ahead of the surgeon's arrival. This expedites the movement of cases on an active service. The spinal needle is inserted; the position is corrected; blood pressure and, if necessary, intravenous fluid apparatus are adjusted by the time the surgeon arrives in the operating room. The subsequent scrub-up period, in which previously the entire technic had to be hurriedly performed, is utilized to make the subarachnoid injection and to observe deliberately the

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

From the Department of Anesthesiology, St. Luke's Hospital.

thetic drugs are injected into the subarachnoid space. Probably no other tissue area in the body could receive the injection of between 700 to 825 mg. of procaine in a 5 per cent solution within a short period without producing toxic effects. Up to the present, anesthesiologists have always rightly used the 2 per cent solution with much caution in work with regional block anesthesia.

The immediate dilution by the spinal fluid of solutions injected into the subarachnoid space is only one of the safety factors involved. Beyond this, it is possible that the myelin sheaths and nerve tissue in general compete effectively with the blood stream absorption mechanism (a mechanism far from clearly understood) in the fixation or removal of the available procaine in the subarachnoid space. The relatively large portion obtained by the nerve tissue is temporarily fixed there and then is gradually given off to the circulation at a rate easily handled and detoxified by the liver. A more detailed study of human tolerance for the subarachnoid injection of procaine will subsequently be reported.

Summary

The fractional technic of administration will prove of great value in increasing our knowledge of spinal anesthesia. Already it has added to the safety and reliability of the procedure. A simplification of the technic has been described.

We have found that from a low tap unexpectedly large amounts of procaine are frequently required to raise the level of anesthesia to the required site. This fact has been used to attempt to appraise the degree of toxicity resulting from simple absorption after subarachnoid injection of procaine. From our results this toxicity is mild.

Discussion

Dr. Virginia Apgar, *New York City*—Dr. Burford's paper is among the earliest reports of the serial spinal method as observed by anesthesiologists. He has shown that the possibility of intermittent dosage of procaine has made spinal anesthesia much safer for the patient and relieves the surgeon of the worry that the anesthesia will wear off before the end of operation.

This no doubt accounts for the great popularity of the method among surgeons. The intermittent dosage appeals to anesthesiologists as the physiologic way to administer a drug to a patient. Spinal, as well as intravenous, anesthesia is now approaching the individual dosage of the anesthetic agent permitted by the inhalation route.

His observations as to the low toxicity of 5 per cent procaine introduced into the spinal fluid we can corroborate with our experience in the use of doses as high as 1,575 mg. during the course of four hours. There has been no evidence as yet of damage to the patient resulting from the metabolism of these large doses, even in cases with severe liver damage.

We should like to differ slightly with a few of Dr. Burford's observations. After using the method in 250 cases, we feel that the mattress as described by Dr. Lemmon has been most useful. Our only failures to introduce the needle (3 cases) occurred when a makeshift mattress was used. It is possible to cut over an operating room mattress, or a regular one, and recover it with a water-repellent material instead of buying the rather expensive ready-made one. However, we shall try Dr. Burford's method of supporting the lower thoracic spine with folded sheets placed above the needle.

We still worry about the angle at which the patient lies on the table. In some cases with 5 per cent procaine, it was impossible to get a good perineal anesthesia in the head-down lithotomy position, while the anesthesia of the trunk and thorax was more than desired. This has led us to use spinocaine much more often than previously for cases in the Trendelenberg position. This was also true of a patient with a popliteal aneurysm who was in the prone position for five and one-half hours. Five per cent procaine did not produce sensory anesthesia, but spinocaine proved satisfactory.

Dr. Burford does not usually use any vaso-pressor drug with this method. We have found their use imperative in abdominal cases. As to the best drug or method of administration we are not decided. An initial dose of ephedrine usually prevents an initial fall in blood pressure, but a second dose during a period of hypotension often has no effect. Recently, we have been adding a small amount of epinephrine to the second dose of ephedrine on the basis of experimental work suggesting that ephedrine inactivates the enzyme that destroys epinephrine and that circulating epinephrine is necessary for the action of ephedrine. Intramuscular neosynephrin has produced some rather marked swings in systolic pressure, but smaller doses may correct this. Hypotension has been the most frequent operative complication. The main features are a small pulse pressure; often, a low systolic level; a good clinical appearance of the patient; and a slow pulse. Its severity does not parallel the large doses of procaine. A high-oxygen atmosphere often does not improve it.

connection is sufficient on the syringe end. An artery clamp can be used in place of a pet cock for temporarily blocking the lumen.

No compromise, however, can be made with the third original feature of this method—the special malleable spinal needle. This soft, practically unbreakable needle is essential to the safe performance of the technic of continuous spinal anesthesia. The needle has no “spring” to its shaft; it is readily bent and holds any position into which it is molded.

Lemmon's statement that two of the older-type needles were broken in a month should be remembered by anyone undertaking this method. Our own experience has been confined to the special needle and none has broken. However, at least half of the needles withdrawn at the end of the operation are bent at sharp angles which, in many instances, would be sufficient to break the ordinary type of spinal tap needle.

Anyone, then, familiar with spinal anesthesia may undertake this technic with this minimum of special equipment: (1) a malleable spinal needle; (2) fine bore, nonkinking rubber tubing; and (3) a single Luer-loc connection adapted to fit the spinal needle on one side and the fine bore tubing on the other.*

Dosage

In using this fractional technic our most interesting experiences to date have occurred in connection with the amount of procaine that has of necessity been injected into the spinal subarachnoid space to obtain adequate anesthesia.

In the past, our belief, and apparently that of most workers in the field, has been that the toxicity of anesthetic drugs injected into the subarachnoid space is intermediate between the severe reaction produced by intravenous injection on the one hand and the relatively milder effect of subcutaneous injection on the other. This belief is based chiefly on irrelevant work showing a rapid appearance of such drugs as phenolsulfonephthalein and potassium ferrocyanide in the blood and urine after subarachnoid injection. Such drugs, of course, have not the specific affinity for nerve tissue shown by the various local anesthetics. Their behavior should be quite different.

More recently, but preceding the use of continuous spinal anesthesia, we have had reason to question whether a dangerous toxic effect develops from simple absorption alone. Pro-

vided cephalad diffusion and certain motor paralyses do not occur—or when these effects do occur, provided anoxia is prevented—we have reason to question the development of serious absorption toxicity accompanying spinal anesthesia. We reported a technic[†] utilizing routine oxygen inhalation at high tension for the safe use of large dosage subarachnoid injections to produce prolonged anesthesia.

With the advent of the continuous technic it seemed possible to put the problem of toxic absorption from the subarachnoid space to critical examination. If diffusion could be kept minimal by using a technic of injection aimed at that purpose (fine bore needle, low tap, minimal pressure injection), perhaps a considerable amount of procaine could be injected before anesthesia developed to the level necessary for operation. This technic, while at first sight appearing experimental, would utilize the theoretic safety factors of continuous spinal anesthesia—namely, a slow, controlled rise in cord level—to the greatest advantage.

At the same time, these large amounts, if administered without accompanying evidence of reaction, would have a distinct bearing on estimating the importance of systemic toxicity following absorption from the human subarachnoid space.

Utilizing this slow diffusion method, we found that really large amounts of procaine could be, and frequently had to be, injected before anesthesia developed in the operative field and blood pressure began to fall. The first patient under this technic required 825 mg. of 5 per cent procaine dissolved in spinal fluid and physiologic saline solution before anesthesia progressed high enough on the cord to permit the performance of an inguinal herniorrhaphy and before the blood pressure started to fall. This amount was given over a thirty-minute period. Another patient received 800 mg. over a three-quarter-hour period before anesthesia of the upper thigh developed. Several patients of necessity received over 500 mg. procaine in the early minutes before adequate anesthesia was established.

In these cases the correct position of the needle was established by aspiration or by direct observation of the drip of spinal fluid at the end of the operation. None showed evidence of cerebral or cardiovascular effects of procaine overdosage.

This to us indicates a wide margin of safety—considering only toxic effects from absorption into the blood stream—when anes-

EXPERIENCE WITH SULFAPYRIDINE AND SULFATHIAZOLE

WILLIAM D. PROVINCE, M.D., and FREDERICK K. HEATH, M.D., New York City

SULFAPYRIDINE and sulfathiazole became available for clinical use shortly after their introduction—the former in England in 1938 and the latter in the United States in 1939. The following report deals with the experience in their use at the Presbyterian Hospital in New York City during the period from July, 1938, to May, 1940.*

Sulfathiazole is more rapidly absorbed and excreted than sulfapyridine. They both differ from sulfanilamide in their capacity to form insoluble acetyl compounds, which appear in the urine in the form of crystals. In this circumstance they may either cause hematuria by trauma or obstruction by concretion.

Sodium salts of both sulfapyridine and sulfathiazole are available for parenteral administration. In general, 5 Gm. of sodium sulfapyridine given intravenously daily will maintain an effective blood level for a twenty-four-hour period. The more readily excreted sodium sulfathiazole must be given in larger quantities or more frequently to maintain an adequate level. Both of these sodium salts are acetylated in the body and, like the drug from which they are derived, may cause hematuria or obstruction.

There is great individual variation in the metabolism of these two drugs by the patient, and for this reason it is necessary to take frequent blood levels. Some patients have been maintained on 2 Gm. of either drug daily with an effective blood level (5 mg. per hundred cubic centimeters of the free drug), while other patients have required 18 to 20 Gm. daily to reach the same level. These are extremes, and it is true that the general daily requirement is 5 to 6 Gm. This dosage will establish and maintain an effective blood level in the majority of patients.

It is stated in the literature that sulfathiazole is acetylated less than sulfapyridine, and in using the Marshall method this is probably true. However, we have studied 900 blood levels of each drug determined by the modified Werner method. With this method the aver-

age acetylation is about 30 per cent for both drugs.

Toxicity

The toxic manifestations of sulfapyridine and sulfathiazole are summarized in Table 1.

Nausea, vomiting, and anorexia were the most frequently encountered symptoms. The statistics in the table reveal a higher incidence than in most series reported. If nausea or vomiting appeared in a case, it is recorded as such without trying to quantitate it. There is less nausea and vomiting with sulfathiazole. Moreover, these symptoms are qualitatively different, being milder and transient and usually appearing and disappearing in the first twelve to twenty-four hours. With sulfapyridine the nausea is often more severe, prolonged, and detrimental to the patient's morale.

It has been our experience that luminal has been the most helpful agent in controlling these symptoms ($\frac{1}{15}$ to $\frac{1}{8}$ Gm. given by mouth or by hypodermic one-half to three-quarters of an hour before each dose).

The statistics on the presence of crystals in the urine need explaining. The great majority of the sulfapyridine cases were studied during the first year of sulfapyridine therapy when we were not aware of the significance of crystals. Therefore, the higher incidence encountered with sulfathiazole may have been due to more particular attention to their presence.

Hematuria has not been frequent and, again, the lower incidence with sulfathiazole may be due to our increased knowledge of its mechanism. It has been observed, first, that hematuria rarely occurred in patients voiding 1,000 cc. daily and, second, that all the cases of gross hematuria were heralded by microscopic showers of red cells one to two days in advance. Because of these observations when a microscopic hematuria or a decreasing urinary output is discovered, the drug is stopped or the fluid intake is increased. Intravenous sodium sulfapyridine when given in doses larger than 5 Gm. or in the presence of low fluid intake has been a frequent offender.

Dermatitis appeared in 8 per cent of the sulfathiazole cases and in 2 per cent of the sulfapyridine cases. The rashes usually appear from the seventh to tenth day of therapy—in this series, most frequently on the

From the Department of Medicine, College of Physicians and Surgeons, Columbia University, and the Presbyterian Hospital, New York City.

* For much of the sulfapyridine and sulfathiazole used in this study we are indebted to E. R. Squibb & Sons, Merck and Company, Lederle Laboratories, and Winthrop Chemical Company.

We have not found that especially large doses of procaine are necessary to produce the desired level of anesthesia. The largest was 250 mg. in divided doses for a gastric resection.

Pentothal or nitrous oxide are often used to control the retching that occurs in operations on the upper part of the abdomen and to do away with the discomfort of a long operation in the Trendelenburg position.

The incidences of headaches and backaches are no greater with this method in our series than with other methods.

Dr. Burford has brought us many interesting ideas in his paper, and I feel sure that after several years of experience with this new method most of his observations will be found to be accurate.

Mary Putnam Jacobi Fellowship

The Women's Medical Association of New York offers a Mary Putnam Jacobi Fellowship for medical research of one thousand dollars (\$1,000), available October 1, 1942. It is open to any woman doctor, either American or foreign, who is a graduate of a reputable medical school.

Applications for this fellowship must be filed with the secretary of the committee by March 1, 1942, and must be accompanied by statements by persons other than the candidate as to (1) health, (2) educational qualifications, and (3) previous work. The applicant herself should state the problem she proposes to investigate and send her photograph. As it is not practicable for the secretary to write for letters about candidates, applicants should send with their application sufficient data to enable the committee to judge of their respective merits.

The recipient of the fellowship will be expected to give full time to the study of her problem and to make a report for publication at the completion of her research.

Application blanks may be obtained from the secretary of the committee.

ANNIE S. DANIEL, M.D.

AN EXAMINATION AS TO FITNESS FOR MARRIAGE....

.... should mean far more than a test of the blood for syphilis and a cursory inspection for the presence of gonorrhea, says Dr. Robert L. Dickinson in *Clinical Medicine*. It should include a study of the family history for the presence of inheritable diseases; of the personal history, not only for physical diseases but also for psychic tendencies and patterns; and a complete general examination, including the conformation and functions of the genital organs.

Preventive medicine is rapidly taking precedence over curative medicine, and people expect physicians to prevent disorders that are preventable.

Divorce is a social disorder (and frequently also a personal one) and can, in most cases, be prevented by proper and adequate instruction and training of the young couple before marriage. The frankness of youth is amazing, but its ignorance is appalling.

The successful premarital consultation requires a physician who is trained in its technics, and must be thoroughly individualized. It should include a study of the hereditary factors on both sides; of the training, knowledge, and adaptability of both the young people; and of the probability of their ready adjustment to the sexual relationship and to childbearing. Instruction should be given as and where it is needed, and a thorough working knowledge of the technics of contraception is the only sure path to planned parenthood, which is a powerful prophylactic against divorce.

This country is not yet ready for the legal enactment of such ideal premarital requirements, but the medical profession should be educating the people to the point where such examinations become the voluntary custom of all reasonably civilized people. Only then can such measures be safely enacted as a legal code.

TABLE 2.—ANALYSIS OF PNEUMONIAS WITH MORTALITY

	Drug	Number of Cases	Mortality, Percentage	Number of Bacteremia	Mortality, Percentage of Bacteremias
Pneumococcus	S. P.	100	10	13	30
Lobar pneumonias	S. T.	34	0	1	0
Pneumococcus	S. P.	48	10	3	100
Bronchopneumonias	S. T.	21	5	0	0
Nonpneumococcus	S. P.	28	7.1	0	0
Lobar pneumonias	S. T.	3	0	0	0
Nonpneumococcus	S. P.	26	11.5	1	100
Bronchopneumonias	S. T.	12	16.6	0	0
Serum and chemotherapy		21	14	5	40

Heidelberger¹ or the usual rabbit serum supplied by the commercial laboratories or the New York City Department of Health. In all cases 100,000 units or more were given until the precipitin test for circulating antibody showed an excess. The usual preliminary precautions were carried out and no untoward reactions occurred.

Results

Between July, 1938, and May, 1940, there were 272 adult cases of lobar pneumonia and bronchopneumonia treated in the Presbyterian Hospital with chemotherapy, with an uncorrected mortality of 8.5 per cent. This does not exclude those patients who arrived at the hospital moribund, those who received less than 5 Gm. of drug, or those who died in less than twenty-four hours of admission.

For purposes of analysis the cases were separated into two groups: (1) the pneumococcal pneumonias and (2) the nonpneumococcal pneumonias, which did not include the so-called "atypical" or "virus" pneumonias but which presented enough suggestive features to warrant a trial on chemotherapy. Bacteria other than pneumococci—i.e., hemolytic streptococcus, hemolytic *Staphylococcus aureus*, etc.—were isolated from the sputums of some of these cases.

Each of the above groups were subdivided into (a) the lobar pneumonias treated with sulfapyridine and sulfathiazole; and (b) the bronchopneumonias treated with sulfapyridine and sulfathiazole, making eight subdivisions as indicated in Table 2.

In comparing the results of chemotherapy in the pneumococcal lobar pneumonias in this series, it is seen that there were 100 cases treated with sulfapyridine, with 10 deaths, a mortality of 10 per cent. Among these cases there were 13 with bacteremia, with a 30 per cent mortality. There were 34 sulfathiazole-treated cases of lobar pneumonia without a fatality. In this group there was only 1 bacteremic case and he recovered.

The pneumococcal bronchopneumonias numbered 48 treated with sulfapyridine, with a mortality of 10 per cent. In this group there were 3 patients with bacteremia, all ending fatally. Two of these patients came to the hospital with an agranulocytosis due to amidopyrine and died terminally of their pneumonias. The third was a 73-year-old patient with a carcinoma of the esophagus who developed the pneumonia following gastrostomy. There were 21 cases of pneumococcal bronchopneumonia treated with sulfathiazole, with a 5 per cent mortality. None of these was bacteremic.

There were 28 nonpneumococcal lobar pneumonias treated with sulfapyridine, with no bacteremic cases and a mortality of 7.1 per cent. Three cases were treated with sulfathiazole; none was bacteremic and all survived.

The last group consisted of the nonpneumococcal bronchopneumonias, of which there were 26 treated with sulfapyridine. The mortality in this group was 11.5 per cent. One of these cases was bacteremic; it was due to *Bacillus Friedländer* and at autopsy showed an abscess of the liver secondary to a perforation of the duodenum. There were 12 cases of nonpneumococcal bronchopneumonia treated with sulfathiazole, with a mortality of 16.6 per cent and no bacteremias.

Comment

It is interesting to note that the mortality rates in all varieties of pneumonia treated with sulfapyridine were approximately the same—i.e., around 10 per cent. On the other hand, in 55 cases of pneumococcal pneumonia treated with sulfathiazole the mortality was 1.8 per cent.

In analyzing this apparent difference in the effectiveness of the two drugs, the following facts must be borne in mind. Fifty-two per cent of the series treated with sulfapyridine were under treatment by the third day of the disease. On the other hand, 73 per cent of

TABLE 1.—COMPARATIVE TOXICITY OF SULFAPYRIDINE AND SULFATHIAZOLE

	Sulfapyridine (202 Cases)		Sulfathiazole (178 Cases)	
	Num- ber	Per- cent- age	Num- ber	Per- cent- age

Diarrhea	0	0	1	0.5

ninth day. The eruption that appears with sulfathiazole has been usually of the erythema nodosum type, characterized by rounded, red, raised tender areas over the extensor surfaces of the elbows and the shins. Rarely, it has appeared on the face and trunk as well. In 3 cases the rash was accompanied by conjunctivitis and joint pains. The sulfapyridine eruption has been of the maculopapular, erythematous type, most frequently seen on the thorax and abdomen.

Drug fevers usually appear after the first week of chemotherapy; the temperature is usually characterized by a slow rise but may be accompanied by chills and fever of the spiking type. With the appearance of a rash or fever the drugs are stopped.

Anemias were rare, comprising only 2 to 3 per cent of the toxic manifestations. These were of two varieties: (1) the acute hemolytic variety, coming on in the first three days of therapy; and (2) the more usual type where the red blood count drops off more slowly over a period of days or a few weeks. Leukopenias were rare and no purpuras were seen. None of these untoward manifestations progressed following cessation of therapy.

Peripheral neuritis is rare and has not been seen with sulfapyridine. It has appeared three times in mild degree with sulfathiazole. In each instance it appeared two to four weeks following cessation of therapy and was characterized by pain, paresthesia, and slight motor weakness, clearing spontaneously. The peroneal nerve was involved in 1 case and the ulnar and peroneal nerves in the other 2 cases.

Certainly, from the patient's point of view, sulfathiazole is a more desirable drug to take than sulfapyridine. It gives less nausea, anorexia, and vomiting. With regard to the other toxic manifestations it is comparable to sulfapyridine.

Management of the Pneumonias

Between July, 1938, and May, 1940, 272 cases of pneumonia were treated by chemotherapy and, of this group, 21 cases received serum in conjunction with chemotherapy. Unfortunately, alternate cases were not treated with the two drugs. During the winter of 1938 to 1939 the majority of the cases were treated with sulfapyridine, and during the winter of 1939 to 1940 the majority received sulfathiazole.

The diagnosis was based upon the history, physical findings, and an x-ray of the chest in every case. The criteria for the diagnosis of lobar pneumonia were sudden onset with chill, fever, cough, rusty sputum, and chest pain with consolidation of lobar distribution on physical examination or by x-ray. Bronchopneumonia was diagnosed in the absence of a typical history or when patchy consolidation was noted on physical or x-ray examination. Furthermore, all postoperative pneumonias were included under bronchopneumonia.

At least one and, in negative cases, usually two or more examinations of sputum for pneumococci were made. This included Neufeld typing, direct culture, and mouse inoculation, all of which were done with each sputum. Blood cultures were done in 91 per cent of the cases before administration of any therapy. If indicated, they were repeated. Complete blood counts were done on alternate days and in many cases they were done daily. Blood levels (modified Werner method) were taken the morning following initiation of chemotherapy and on alternate days thereafter. Only the unconjugated or "free" drug level is mentioned in this paper. In most cases fluids were forced to between 2,500 and 3,000 cc. daily and the output measured.

When the necessary diagnostic data had been secured, chemotherapy was begun. The initial dose with both sulfapyridine and sulfathiazole was rather uniformly 2 Gm., followed by 1 Gm. every four hours. But since an attempt was made to keep the blood level approximately 4 to 6 mg. per hundred cubic centimeters, the subsequent dose varied with the blood level. The sodium salts of sulfapyridine and sulfathiazole were used intravenously when it was desired to secure a high initial blood level concentration, when difficulty in maintaining concentration by mouth was encountered, or when oral medication was impossible.

Serum, when employed, was concentrated rabbit globulin prepared by Dr. Michael

The authors wish to thank Drs. A. R. Dochez and Yale Kneeland, Jr., for their supervision and many helpful suggestions.

SULFATHIAZOLE PER SE IN THE TREATMENT OF LOBAR PNEUMONIA

To the Editor:

March 1, 1941

In reading through recent articles referable to the treatment of pneumonia with sulfathiazole, I thought of the paradox of the treatment therein prescribed as compared to that of a case of lobar pneumonia treated by me. In my case, as differentiated from those described, there were no hospital facilities, no nursing attention, practically no care, no hygiene, no laboratory procedures, and no x-rays or any of the modern diagnostic or therapeutic aids. If ever there was a possibility of finding out the value of a medicament per se, this was an ideal case. In fact, the lack of hygiene and proper care and attention put the medicament to its greatest test—and it won. All the patient received was sulfathiazole and small amounts of liquids.

This patient, a Chinese schoolboy, aged 16, weighed 110 pounds and was 5 feet, 5 inches tall. He was in a room 40 by 20 feet. This room was subdivided into ten booths, the partitions being 6 feet high. Each booth had a single bed, dresser, and chair. There were three large windows on one side of the room. I managed to have one of these opened, but doubt that it was kept open very much. The window shades were always drawn. Thus, there was a minimum of fresh air and sunshine in this bedroom where 10 persons slept. The toilet facilities were in the next room, where, despite his critical condition, the patient was forced to go. He was mostly alone during the day except for an occasional visit by his uncle, who came up from downstairs to give him his medication and liquids. He was in bed, clad in pajamas and some over clothing. No skin care was given.

The temperature, pulse, and respirations were noted by myself once daily. No laboratory aids

such as blood counts and concentration levels, sputum examinations, x-rays, etc., could be used. Nursing care was nil. This patient just lay there, and with the help of sulfathiazole and small amounts of liquids he recovered.

The patient became ill January 24, 1941. On this date he had a severe chill, fever (104 F.), pain in the right side, cough, dyspnea, flushed cheeks, and scanty viscid sputum. On examination, there were dullness, increased vocal fremitus, tubular breathing, and fine crepitant rales over the lower left lobe.

The first day $1\frac{1}{2}$ Gm. of sulfathiazole was given every four hours. The second day, $\frac{3}{4}$ Gm. was given every four hours. On the third, fourth, and fifth days the dose was $\frac{1}{2}$ Gm. every four hours.

After the first thirty-six hours, when I visited the patient, he was sitting up, looking cheerful and well. The cough was slight, and his temperature was 99.4 F. The rales were more bronchovesicular. On the fifth day all signs and symptoms disappeared.

This patient recovered despite every medical and nursing disadvantage, with one exception. The treatment was solely dependent on the medicament—sulfathiazole. The cure was about as rapid as the hospitalized cases receiving every modern facility. The only unknown factor here is, how the patient would have fared without the sulfathiazole. The probabilities are obvious, and it seems that this was an ideal case to note the potentialities of sulfathiazole per se.

453 Western Avenue
Albany, New York

MEDICOMILITARY SYMPOSIUM ON NUTRITION

"Nutrition in the Army" will be the subject of a symposium for Medical Department Reserve Officers on Tuesday evening, January 13. The meeting will be held at 8:30 p.m. in the Federal Building at 90 Church Street, New York City.

Participants in the symposium will include Colonel Samuel Adams Cohen and Colonel H. I. Teperson of the Medical Corps Reserve, Lieutenant Colonel James A. Tobey of the

Sanitary Corps Reserve, and Major Louis Griessman of the Veterinary Corps Reserve. Colonel Milton I. Strahl, Medical Corps Reserve, is chairman of the executive committee in charge of this event.

An exhibit on army nutrition will also be shown. The entire program is under the supervision of Lieutenant Colonel William C. Lippold, M.C., U. S. A., chief of the medical section of the Second Military Area.

the sulfathiazole-treated cases were receiving the drug at this early date. In other words, the patients who were treated with sulfathiazole arrived at the hospital earlier on the average than those in the sulfapyridine series. Since in the majority of cases the bacteremia does not appear until the third day of the disease, this means that the cases treated with sulfathiazole were receiving chemotherapy before the expected day of sepsis. This fact may explain why the bacteremic rate and mortality were lower in the sulfathiazole cases.

The distribution of the types of pneumococci in lobar cases was about the same.

The majority of the cases were white, with the male sex predominating. In spite of the opinion that Negroes offer poor resistance, 37 were treated without a fatality. Eighty per cent of the sulfapyridine and all of the sulfathiazole deaths occurred in patients over 60 years old.

Although at first it was thought that there was a difference in time of crises with the two drugs, no essential difference was found. Approximately one-third to one-half had crises in the first twenty-four hours, and three-quarters to four-fifths had a crisis in forty-eight to seventy-two hours with the use of either drug.

How long should chemotherapy be continued? There is no definite answer to this question. Each case is a problem unto itself. In the first year of chemotherapy the cases received an average of 27 Gm. of sulfapyridine over a period of five days; a study of the cases revealed a small group of patients who suffered relapses when only 10 to 25 Gm. had been administered. During the second year, when the change was made to sulfathiazole, a larger dose was employed. An average of 45 Gm. was given during a period of seven days. This larger dose and longer period of therapy appeared to result in fewer relapses.

The average period of hospitalization was nineteen to twenty days. This figure is uncorrected for other conditions irrelevant to the pneumonia.

The various chemotherapeutic agents are indicted, and rightly so, for their toxic properties, but little is said about the marked reduction in toxic phenomena associated with the pneumonia *per se*. It is noteworthy that only 1 patient out of 272 had sufficient distention to warrant energetic treatment directed toward decompression. Second, there has been a marked decline in the need and use of oxygen in pneumonia. Finally, there is an

increased sense of well-being in most cases soon after drug administration is begun.

In this series no correlation of blood level with crisis could be found. If there is a critical level for crisis it was not discernible.

There were 21 cases that received both chemotherapy and serum. This group represented the most severely ill patients in the series. Their average age was 50. There were 5 bacteremic cases, with 3 deaths—a mortality of 14 per cent for the entire group. The age of these 3 fatal cases was well above average. Two of them were due to *Pneumococcus* type III and were complicated by asthma and agranulocytosis due to aminopyrine, respectively. The third death occurred as a relapse in a *Pneumococcus* type III pneumonia. The group is too small to draw any conclusions.

The pneumococcic cases were pooled and the incidence of complications were compared. Pleural effusions occurred in 11 to 12 per cent and empyema in 3 per cent with both drugs. Relapses took place in 12 per cent of the sulfapyridine cases and in 9 per cent of the sulfathiazole cases. The relapses represent inadequate therapy as to daily dosage and duration.

Summary and Conclusions

1. Our experience with sulfapyridine and sulfathiazole in the treatment of various types of infections between July, 1938, and May, 1940, is herewith reported.

2. Nausea and vomiting are less frequent and less severe with sulfathiazole than with sulfapyridine. Other toxic manifestations occurred with about equal frequency. Provided that proper precautions are taken during the course of drug administration, all of these toxic manifestations can be prevented or controlled.

3. Altogether, 272 cases of pneumonia were treated with chemotherapy with a mortality of 8.5 per cent.

4. The mortality rate in 100 cases of pneumococcic lobar pneumonia treated with sulfapyridine was 10 per cent.

5. Thirty-four consecutive unselected cases of pneumococcic lobar pneumonia were treated with sulfathiazole without a fatality. Only 1 of these cases was bacteremic.

6. The results of chemotherapy in cases of pneumococcic bronchopneumonia are approximately the same as in lobar pneumonia.

FIGS. 1 and 2.

vironment. As is so often true in science, the answer also sets a problem.

These results, which may be characterized as revolutionary, have a distinct bearing on the problem of stability of racial types. If environment affects physical type then it would explain the overlapping of our white subraces of today, for mankind has in all probability been subject to this change, time and again, in his

wanderings over the earth. Man has been moving for centuries, and there are no distinct records of the changes effected by these wanderings. Thus, the picture of race shifts from one of stability to one of recurrent changes.

From a surgical point of view, if we are to adhere to these physical measurements in utilizing the rhinometric instruments for our guidance, we cannot help but err in the ma-

THE IDEAL NOSE

ALBERT A. CINELLI, M.D., F.A.C.S., New York City

IN THE last decade much has been written in plastic textbooks and in the literature on the physical measurements of the nose for rhinoplasty. Many new instruments (profilometers, photometers, rhinometers, etc.) have been devised to measure the various angles of the nose. This has been an outgrowth from the architectural pattern of the face fashioned from the works of Schadow.¹

Briefly, in Fig. 1 the profile angle (C) varies from 25 to 35 degrees with 30-degree angle considered the ideal measurement for rhinoplasty. It is formed by a line (A) drawn from the frontal protuberance to the chin, with another line (B) from the root of the nose along the dorsum to the tip. Any marked excursion from this mathematical pattern results in either a convex (hump) or concave (saddle) nose.

Another mathematical dictum is that the length of the nose—that is, from the root to its tip—is the same or slightly shorter than the chin line (a line drawn from the base of the columella to the chin).

The septolabial angle (D) varies from 90 to 105 degrees and is formed by the columella with its junction of the upper lip. A long nose will shorten this angle and conceal the beauty of the mouth. An extremely short nose increases the angle with a marked accentuation of the upper lip. The ideal measurement is about 90 degrees.

The facial planes exhibited on a frontal view by this canon are interesting—Fig. 2. Four parallel lines running, respectively, through the hairline, the root of the nose, the base of the nose, and the chin will divide the face into 3 equal parts.

The position and size of the eyes are most important in the pattern. The width of an eye, the space between the eyes, and the width of the nose are equal in size.

The mouth must blend somewhere in the physical pattern; most pleasing to the eye would be about one-third the distance from the columella to the chin line.

The question that confronts us is: Are we to be guided in our nasal corrections by these mathematical formulas? If not, then why all these rhinometric instruments, the different canons, dissecting the entire face into a mathematical pattern of angles and squares?

Do these serve more of an academic interest than of a surgical value or both?

What could be more fitting as an answer than to refer to the real beauties as represented by the great masters. Fig. 3 is the Italian beauty, Beatrice d'Este, painted by Leonardo da Vinci. The septolabial angle is 110 degrees and the facial compartments are unequal. Fig. 4 is an English beauty painted by Rothstein of the British School. Here the discrepancy in these physical patterns is even greater. The septolabial angle is 123 degrees, the profile angle is 37 degrees, and the facial compartment at the base of the nose is asymmetric.

Fig. 5 is an English beauty painted by Dante Gabriel Rossetti of the British School. Here the hairline and the base line of the nose do not synchronize in a mathematical pattern in this priceless gem. Fig. 6 is a portrait of a Dutch beauty painted by Gari Melchers and is far from keeping in harmony with these architectural designs as is apparent.

From these immortal paintings briefly, then, we observe that beauty is not a physical pattern of squares and angles, fashioned on a mathematical basis. It is rather something indefinable by which our eyes, hands, and soul are artistically and culturally gifted to create the integral parts of the face into a harmonious symphony of aestheticism.

From an anthropologic point of view, we find ourselves more in a quandary.²⁻⁴ The cephalic, orbital, and nasal indices vary not only among the races but surprising enough even in the same family. Boas⁵ found in his experiments that the children born in this country differed considerably from the children born in Europe from the same parents. Fortunately, the conditions of this inquiry were such that two possible causes for the change in type could be eliminated at once. Change through intermarriage was excluded because the parents of the European-born children and the American-born children were the same. The possibility of selection was also precluded because the time involved was so short. The residual possible cause was, therefore, to be seen in the effect of the American physical environment on the European-born types. Just what is meant by environment? It might cover climate, eating habits, or perhaps an unidentified factor of physical en-

Therapeutics

CONFERENCES ON THERAPY

THESE are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the February 1 issue and will concern "Treatment with Sulfonamide Drugs."

Hypnotics and Sedatives

DR. McKEEN CATTELL: Today we are to have a discussion of the hypnotic and sedative drugs to be opened by Dr. Gold.

DR. HARRY GOLD: I have here a list of the more important drugs that are useful in producing sedative and hypnotic effects: (1) bromides; (2) chloral hydrate; (3) paraldehyde; and (4) barbiturates (barbital, phenobarbital, pentobarbital sodium, amytal, evipan).

We might also add sulfonal and trional and various derivatives of urea, such as bromural, adalin, carbromal (sedormid). Pharmacologically, these compounds are distinguished in part by the fact that while they produce sedative effects they do not bring about deep narcosis even in toxic doses.

Alcohol is effective in producing hypnotic effects, but it presents special well-known features that make it undesirable for general use in that way.

Chemical enterprise has been intense in the field of synthesis of sedative agents, and literally hundreds of agents related to chloral, urea, and barbituric acid have been made. Scores of them have been introduced into therapeutic use. It is my belief that the small list given above will satisfy all the needs that can be satisfied by known sedative and hypnotic agents.

Sedatives versus Hypnotics.—The first matters I wish to consider are the terms "hypnotic drug" and "sedative drug." A recent paper on hypnotics in the *J.A.M.A.* defined hypnotics as "drugs that induce sleep," and sedatives as agents which "decrease the sensitivity of the central nervous system," although it was made clear that no sharp distinction can be drawn between them. I think these terms have rendered poor service, and perhaps we ought to consider abandoning them. If we do that we may succeed in time in relinquishing an incorrect idea which they tend to pro-

mote. The terms sedative and hypnotic should be used, I think, to label effects, not drugs, because it is the same drug that causes both effects. The same action operating under different conditions gives different results. A dose of 0.3 Gm. (5 grains) of barbital will quiet the patient and reduce nervousness during the day. The patient may be aware of some dulling of the perceptions or mentation, but he does not fall asleep. The same dose of barbital given at bedtime, with all other factors present conducive to sleep, produces sleep. Occasionally, it is a matter of doses, somewhat larger doses being necessary for sleep. The grouping of drugs as sedatives and hypnotics is often attempted. Physicians sometimes prescribe phenobarbital to be taken during the day and then barbital at night, in the belief that one is just a sedative and the other a hypnotic. I believe that such a distinction has no validity.

Mode of Action.—This whole group of substances depresses the brain. Thresholds are raised. Changes are produced in the sensory, the motor, the intellectual, the autonomic, and the psychic reactions. Reflexes are depressed. There is no reason to suppose that any portion of the brain escapes their action. The net result of this depression is an altered nervous state, which varies greatly from person to person. In general, they tend to produce a feeling of lassitude, diminished mentation, a disinclination to mental and physical activity. Emotional tension, agitation, and anxiety are often relieved during their action. The mood is sometimes changed from one of depression to one of pleasant calmness or even elation.

This depression of the brain usually results in mental and physical rest. And that is the main objective. At night it promotes sleep.

It is not so in all patients, however. In many, the results are distinctly unpleasant

FIG. 6.

majority of cases. In the first place, measuring the nose directly after an operation to ascertain whether or not we have the proper aesthetic measurements does not take into consideration the swelling and edema that are always associated in these cases through local

infiltration, trauma to tissue, bleeding, etc. It does not take into consideration the future contraction that is going to take place. It does not take into consideration the retraction of the tip which always follows and, at times, may ruin an apparent good result.

The philosopher and anatomist, Bell,⁶ in speaking of attaining beauty, said: "The artist is not to slight nature or avoid it, but to study it deeply, as the only source of improvement. He should study the quality of smile, the eloquent eyes, the formation of the forehead, the depth of the eyes, etc., and thus he passes from point to point, from one feature to another, the nose, the ear, exaggerating a little the outline of whatever indicates the higher and purer qualities, and avoiding what is low or whatever is associated with the baser human passions or with the form of the brutes and by insensible gradations and long contemplations of what is highest and best, he acquires from nature, that idea which is in his mind, the perfection of form."

A countenance that in ordinary conditions has nothing remarkable may become beautiful in expression. It is expression which raises affection, which dwells pleasurably or painfully in the memory.

In rhinoplasty let us not analyze these cases in physical terms of angles and squares which rob us of initiative and the burning desire for creation. The wonders of the Renaissance lay claim to give nature the expression and feeling of beauty which is seen through the artist's soul. The inspiring works of Leonardo da Vinci, Michael Angelo, and the divine Raphael who portrayed the spirit of that age are the real creators of beauty personified in art.

"La beauté est un des plus grands mystères de la nature."

As Voltaire aptly remarked: "Beauty to the toad is its mate."

Therapeutics

CONFERENCES ON THERAPY

THESE are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the February 1 issue and will concern "Treatment with Sulfonamide Drugs."

Hypnotics and Sedatives

DR. McKEEN CATTELL: Today we are to have a discussion of the hypnotic and sedative drugs to be opened by Dr. Gold.

DR. HARRY GOLD: I have here a list of the more important drugs that are useful in producing sedative and hypnotic effects: (1) bromides; (2) chloral hydrate; (3) paraldehyde; and (4) barbiturates (barbital, phenobarbital, pentobarbital sodium, amytal, evipan).

We might also add sulfonal and trional and various derivatives of urea, such as bromural, adalin, carbromal (sedormid). Pharmacologically, these compounds are distinguished in part by the fact that while they produce sedative effects they do not bring about deep narcosis even in toxic doses.

Alcohol is effective in producing hypnotic effects, but it presents special well-known features that make it undesirable for general use in that way.

Chemical enterprise has been intense in the field of synthesis of sedative agents, and literally hundreds of agents related to chloral, urea, and barbituric acid have been made. Scores of them have been introduced into therapeutic use. It is my belief that the small list given above will satisfy all the needs that can be satisfied by known sedative and hypnotic agents.

Sedatives versus Hypnotics.—The first matters I wish to consider are the terms "hypnotic drug" and "sedative drug." A recent paper on hypnotics in the *J.A.M.A.* defined hypnotics as "drugs that induce sleep," and sedatives as agents which "decrease the sensitivity of the central nervous system," although it was made clear that no sharp distinction can be drawn between them. I think these terms have rendered poor service, and perhaps we ought to consider abandoning them. If we do that we may succeed in time in relinquishing an incorrect idea which they tend to pro-

mote. The terms sedative and hypnotic should be used, I think, to label effects, not drugs, because it is the same drug that causes both effects. The same action operating under different conditions gives different results. A dose of 0.3 Gm. (5 grains) of barbital will quiet the patient and reduce nervousness during the day. The patient may be aware of some dulling of the perceptions or mentation, but he does not fall asleep. The same dose of barbital given at bedtime, with all other factors present conducive to sleep, produces sleep. Occasionally, it is a matter of doses, somewhat larger doses being necessary for sleep. The grouping of drugs as sedatives and hypnotics is often attempted. Physicians sometimes prescribe phenobarbital to be taken during the day and then barbital at night, in the belief that one is just a sedative and the other a hypnotic. I believe that such a distinction has no validity.

Mode of Action.—This whole group of substances depresses the brain. Thresholds are raised. Changes are produced in the sensory, the motor, the intellectual, the autonomic, and the psychic reactions. Reflexes are depressed. There is no reason to suppose that any portion of the brain escapes their action. The net result of this depression is an altered nervous state, which varies greatly from person to person. In general, they tend to produce a feeling of lassitude, diminished mentation, a disinclination to mental and physical activity. Emotional tension, agitation, and anxiety are often relieved during their action. The mood is sometimes changed from one of depression to one of pleasant calmness or even elation.

This depression of the brain usually results in mental and physical rest. And that is the main objective. At night it promotes sleep.

It is not so in all patients, however. In many, the results are distinctly unpleasant

and objectionable. In some, restlessness is induced. The stupor is often attended by wakefulness. As Dr. Wolff and his associates experienced in one of their studies, anxiety may not be relieved but increased. The difficulty in mentation and the lethargy may be attended by an unpleasant rush of thoughts that create bewilderment, fear, and increased anxiety. Confusional or delirious states are not at all rare after even ordinary doses of these agents, especially in elderly patients. Elderly people are sometimes frightened by the strange sensation that seems to put wakefulness beyond their control.

I want to lay stress on the point that the *quality* of the result obtained with this group of depressants depends largely on the kind of mental organization on which the drug is acting. Perhaps we may have some comment on the opinion that the personality of the patient is more often the reason for the failure of one of these agents to provide the desired therapeutic effects than the fact that the wrong member of this group was used. Indeed, the same person in different mental states responds differently.

The greatest diversity in the response to these depressants is encountered among different individuals. In one, $\frac{1}{2}$ grain of phenobarbital causes mild depression with refreshing sleep. Another is hardly aware of the effect of three times as much. In another, a dose of 2 grains of phenobarbital sodium is given subcutaneously to promote sleep. He falls asleep but awakens three hours later and receives another dose of 2 grains. After three days of this treatment, new complaints arise—weakness, drowsiness, and stupor during the day; he falls asleep during a conversation. Despite this, sleep remains fitful and interrupted at night. The possibility of a complicating disease presents itself—dehydration, acidosis, or uremia. These new symptoms, however, turn out to be the result of cumulation of depressant effects of these drugs in one who is resistant to their hypnotic effects. The symptoms disappear completely when the drug is withheld for two or three days. There are many patients whose insomnia is not readily controlled by depressant drugs, and in the endeavor to enforce sleep by large doses a disagreeable “hangover” and stupor lasting for a day or two results.

When a patient is particularly resistant to the hypnotic effects, it is a common practice to increase the dose until sleep is produced. But in the process of the induction of sleep, as well as in the process of recovery, there are

apt to be periods of restlessness which are of the same nature as the periods of confusional unrest in the course of the induction of ether anesthesia. An endeavor to abolish this unrest by larger doses only serves to increase it after a temporary deepening of the narcotic effect. The spontaneous unrest has here been increased by the drug, and the only effective way of overcoming it is to discontinue the drug for a few days until most of it is eliminated.

This brings up another important question. Are there any significant qualitative differences in the action of the group of depressants? If we fail to secure the necessary mental and physical rest with one, are we likely to obtain it with another?

There is some experimental proof to the effect that the pattern of action on the central nervous system is not the same for the different members. Numerous illustrations can be cited. Saperstein and Wallace found that the aftercontraction (recruitment phenomenon) following tension of voluntary muscles against resistance was fairly regularly abolished by 2 Gm. of sodium bromide, while depressant doses of chloral or barbital were much less constant in their effect upon this function. In experiments on birds it has been shown (Steinmetzer) that one member of this group is more active in abolishing the postural and clasp reflexes than another. For example, it was found that a dose of chloral, which did not produce sleep in the hen, made the hen fall off the perch. It abolished the postural and the clasp reflex in the hen. On the other hand, when a large dose of one of the other hypnotics, such as sodium barbital, was given, the hen fell asleep but continued on its perch without any serious interference with the postural reflex. If, however, the doses were increased, the hen fell asleep and also fell off the perch. There is also some evidence assembled by Pick that chloral, paraldehyde, and other methane derivatives exert a relatively greater action on the cortex in contrast to the barbiturates, which exert a relatively stronger action on the brain stem. Koppányi, Gruser, and others found that the peripheral action of different barbiturates exhibit a different pattern: amylal, pernoston, pentobarbital, and very large doses of barbital block the peripheral vagus, while phenobarbital does not.

Facts such as these indicate that there might be some clinical conditions that would be more favorably influenced by one of these depressants than by another.

What these conditions are or even whether they exist has never been satisfactorily determined.

All that the literature contains are records of uncontrolled experiences. Sollman describes phenobarbital as a good hypnotic agent. Grabfield, on the other hand, describes it as a poor hypnotic and advises against its use as such. Diethelm believes that the difficulty in falling asleep is best treated with paraldehyde and chloral and that broken sleep or sleep of short duration is best treated by the barbiturates. Travell and Hanlon made some observations on barbiturates in different forms of sleeping difficulties and found that these drugs were effective regardless of whether the insomnia was in the nature of a difficulty in falling asleep or in the nature of broken sleep or short duration of sleep. Diethelm advises 1-Gm. doses of barbital for the insomnia of depression states and 0.2-Gm. doses of phenobarbital in senile insomnias. He also recommends a combination of barbital and phenobarbital as possessing special virtues.

These are illustrations of the intangible and contradictory nature of the testimony in regard to qualitative differences between these depressant agents. Scientific clinical investigation has never been put to work on this subject.

We cannot dismiss the possibility that occasionally qualitative effects might be secured with one of these agents when another fails. The way to find out, as far as I can see at the present time, is simply by the method of trial and error. There is, however, a right and a wrong way of going about it.

I should like to urge strongly that when you do shift from one to another of these depressant agents you should not abandon any one drug until its full power to produce the desired effect has been exhausted. Start with a small dose of one of them and, if the effect is insufficient or excessive, do not abandon it for another preparation but reduce the dose or raise the dose before trying another member. Much of the difference that we commonly encounter between the various agents of this group is due to the fact that we compare doses that are not comparable. One author, for example, referred to amytal as depressing the heart and the blood pressure more than other barbiturates, but he gave doses of 0.4-Gm. of amytal and 1 Gm. of barbital. In this way, in terms of potency, he gave twice as much amytal as barbital, because amytal is five times as potent a substance as barbital. The fatal

dose of amytal is about 60 grains and of barbital about 300 grains.

I have a strong suspicion that if we use suitable doses of one of these preparations, doses that are small enough or large enough, many of the differences between them will disappear. The peak effect of materials that are rapidly absorbed is more intense than in the case of those more slowly absorbed. This may result in effects that may have the appearance of a qualitative difference.

This brings us to another point. The various agents do show differences with respect to some of their physical properties, the speed of their absorption, the speed of onset of effects and the duration of their effects, which are of some practical significance.

This whole group of drugs is used for numerous purposes. When they are used as sedatives to control nervousness during the day or to induce sleep in the vast majority of minor disorders of sleep, relatively small doses are given. When, however, they are used as "chemical restraints" in manic psychoses, for the purpose of overcoming convulsions, or as basal anesthetics, the doses are apt to be extremely large.

The term "therapeutic index" is commonly used to describe the relative dangers of different members of the barbituric acid series. Some of the more rapidly eliminated barbiturates have a somewhat higher index than others. For example, it is found in dogs that it takes about 50 per cent more than the anesthetic dose to cause death with barbital sodium by oral administration, whereas it takes somewhat more than double the anesthetic dose of seconal to cause death. This is not a great difference, and few show a difference as large as this, but it might be a consideration when large doses are necessary, as in the treatment of convulsions or maniacal states. The therapeutic index can hardly have any bearing, however, on the selection of barbiturates when they are used in small doses for ordinary sedative and hypnotic effects. The sedative dose of pentobarbital sodium, for example, is about 0.5 to 1.0 mg. per kilogram, and the fatal dose is of the order of 85 mg. per kilogram. The sedative dose of phenobarbital sodium is also about 0.5 mg. per kilogram, and the fatal dose is about 150 mg. per kilogram.

The small differences, therefore, in therapeutic index constitute neither an advantage nor a disadvantage in the use of these compounds for sedative or hypnotic effects. I mention this matter because the "therapeutic

index" is prominently featured in the trade literature.

A word about the bromides. The bromides exert a limited depressant effect in a sense similar to that of carbromal or bromural. Whereas in the case of the barbiturates the depressant effect, depending upon dosage, ranges from one that is barely perceptible to complete narcosis, it is rarely possible to depress to the point of narcosis by means of the bromides with any dosage. Various salts are employed—sodium, potassium, lithium, strontium, and ammonium bromides. Some prefer one; some, another. As far as I know there is no satisfactory reason for these preferences. It has been stated that the sodium and potassium salts are superior to the others. Since these drugs are prescribed in similar doses by weight, one would suspect that the lithium or ammonium salts might give the appearance of being more effective, because a gram of these contains more bromine than a gram of the others. The lithium salt has 92 per cent bromine; the ammonium salt, 81 per cent; potassium salt, 67 per cent; and the sodium salt, only 57 per cent. I can see no significant advantage in the salt containing the larger amount of bromine.

When the bromides are given intravenously in animals, it makes a great difference as to whether one uses the sodium or potassium salt, because the potassium ion is extremely toxic and the animal dies of potassium poisoning rather than of bromine poisoning. The amount of potassium present in even large doses of potassium bromides, such as 4 to 6 Gm., would be only from about 1.25 to 2 Gm. a day. By oral administration that is not likely to produce any potassium poisoning. Irish peasants, eating mainly potatoes, are known to take 50 Gm. of potassium chloride daily. It is, of course, conceivable that in rare cases of advanced nephritis in whom the excretion of potassium may be poor such a factor may need to be taken into consideration.

A fact that doesn't seem to be generally appreciated is that the bromides are slowly excreted. They are rapidly absorbed and, when they enter the blood stream, they are distributed to the extracellular fluids. They apparently do not enter the cell. They behave like the chlorides in that respect. The body tends to keep the total halide concentration fairly constant, so that when the bromides enter the blood stream, halides are excreted by the kidney, both chlorides and bromides. It is generally stated that the kidney cannot

distinguish between chlorides and bromides and, when both are present in the blood stream, they are excreted in proportion to their relative concentrations. For example, if the bromides represent only 10 per cent of the total halides and the rest is the chloride, the kidney will excrete only about one-tenth as much bromide as chloride. The result is that bromide tends to stay in the blood and tissues for a long time.

Some recent experiments by Bodansky and Modell, which were made in the Department of Pharmacology, show that the kidney is not entirely blind to the difference between chlorides and bromides, because they found a somewhat higher concentration of bromides in the blood in relation to chlorides than in the urine and, when they gave a diuretic which caused marked increase in the urine flow, the difference between the blood and urine bromide concentrations tended to disappear. This suggested to them that there is selective reabsorption of bromides which would naturally be interfered with when the urine flow is markedly increased.

If one gives a patient 1 Gm. of sodium bromide daily, the bromide concentration rises rapidly, because only about 10 per cent or less of any dose is eliminated in twenty-four hours. After the first dose the blood concentration may be of the order of 5 mg. per hundred cubic centimeters, but at the end of the two weeks the concentration may reach 80 to 100 mg. per hundred cubic centimeters. If the drug is then discontinued, the blood bromides begin to diminish, and at the end of two weeks the concentration is about half of peak. It takes a month or longer for all of it to be excreted. That, then, is what happens whenever we give a patient one of the favorite bromide prescriptions, such as the National Formulary elixir of triple bromides, which contains a gram of bromides in every teaspoonful. It is not uncommon to find patients taking a teaspoonful three times a day for weeks on end as a sedative.

What is remarkable about this is the fact that the patient seems to be just as much in need of it at the end of a week or two as he was at the beginning, even though at the end the blood bromides were probably 80 to 100 mg. per hundred cubic centimeters. What this means, I am not sure. It can signify the development of a tolerance. Or were the early doses producing any effects?

Those who treat epilepsy with bromides warn that the daily dose should not be interrupted. If they are, there is danger of rapid

return of the epileptic seizures. I cannot quite understand what that warning means, since the interruption of the dose for a day or two is not likely to produce any considerable lowering of the blood bromides. Perhaps there are some here who might want to discuss that point.

Bromide poisoning consists of an intensification of the symptoms of depression. There is fatigue, drowsiness, ataxia, impaired memory, impaired power to grasp ideas, and diminished power of concentration. It is one of the most common causes of drug delirium. Toxic symptoms come on with bromide levels of about 150 to 300 mg. per hundred cubic centimeters of blood under most conditions, but there is a great deal of individual variation in susceptibility.

DR. CATTELL: It is clear that Dr. Gold has a great deal more to tell us, but first it would be desirable to have some comments on the practical experience in this hospital in the use of hypnotics. I wonder if Dr. Wheeler would say a few words?

DR. CHARLES H. WHEELER: The following table represents the use of various hypnotics in the New York Hospital and includes the outpatient department, the wards, and the private service:

Phenobarbital	600,000
Pentobarbital sodium (Nembutal)	40,000
Amytal sodium	10,000
Bromides	7,000
Chloral hydrate	6,400
Barbital	5,000
Paraldehyde	1,000
Amytal	900

The figures represent the number of average therapeutic doses of each drug used in 1939. For example, in that year we used 600,000 average therapeutic doses of phenobarbital, etc. It is interesting that we used fifteen times as much phenobarbital as any other hypnotic in this institution. Another interesting point is that the use of sodium pentobarbital has increased in the past year so that it has been doubled over what it was the previous year. Sodium pentobarbital is twenty times as expensive as phenobarbital and that goes for most of the others.

DR. EUGENE F. DUBOIS: In my own particular type of hospital practice most of the ordering of sedatives is done by the interns.

I am looking with interest on my old friends that we used when I was an intern—the bromides, chloral, barbital, and paraldehyde.

The favorite mixture was the combination of bromide and chloral. I should like to have Dr. Gold's comments. Is there any virtue in giving those two together?

Paraldehyde was almost always used with alcoholic patients. They did not mind the smell. It is hard to use it on a patient who is in a position to object, but I feel it is a valuable drug and here it is way down at the bottom of the list. It is quite evident that phenobarbital is the favorite at the present time, and I find myself using it instead of the other drugs.

I wonder why morphine and its derivatives were left off the list? They certainly act as sedatives and hypnotics.

DR. WHEELER: We left those off, Dr. DuBois, because so much morphine is used under circumstances that I do not think fall into a fair classification of hypnosis, such as postoperatively for coronary occlusion, shock, etc. To include all that would not be possible. Furthermore, morphine is habit-forming and should not be used as a sedative except under unusual conditions.

There is another interesting thing about that table and that is the partition between the ward use and the use on the private patient service. For example, although the bed capacity of the private patient service is small as compared with the wards, the private patient service used much more of the sodium pentobarbital than the wards used. The mixture of three bromides was used almost exclusively on the private service, while on the wards sodium bromide was used almost exclusively. Similarly, phenobarbital in the clinic was always dispensed in tablets, over a million tablets being dispensed during the year in various amounts, while on the private service the elixir of phenobarbital was used almost exclusively. This is hardly used in the ward.

DR. DUBOIS: I think the lesson is obvious. There are a good many differences financially and educationally between the private service and the wards.

Such a name as triple bromides is particularly attractive to the patient. Its supposed triple action is a point stressed in advertising.

One point I think should be remembered about these drugs is that some of them produce skin eruptions in patients who are susceptible.

DR. CATTELL: With reference to the surprisingly large figure representing the consumption of phenobarbital in this hospital, I should like to quote a remark made in one

of the conferences last year. When Dr. Wolff was asked why he used phenobarbital in epilepsy to the exclusion of other barbiturates, he replied that it is the one that he and others had had the most experience with and that it had given satisfactory results, but he suggested that there are probably others equally good. It may, thus, be a matter of tradition which gives preference to the long-established drug, and it is not necessarily indicative of any real advantage of one barbiturate over another.

I imagine the increasing use of sodium pentobarbital is connected with the fact that it is representative of the short-acting barbiturates that have recently been developed. It is eliminated with much greater rapidity than amytal or barbital. I wonder if you would discuss this matter further, Dr. Gold?

DR. GOLD: In regard to Dr. DuBois' question concerning the virtues of the combination of chloral and bromides, I do not believe that there is any satisfactory proof that the combination has any particular merits. Chloral is eliminated fairly rapidly and bromide slowly, so that any mixture containing both, if taken for a protracted period of time, results in progressive accumulation of bromides. The patient is then, by virtue of this difference in elimination, changing the doctor's prescription, since at the end of a week or two he is being affected not by the combination in the bottle but by the revised combination in the body, and this revision continues as the doses are continued.

There seems to be a tendency to revive interest in chloral hydrate, which was one of the first hypnotics of the methane series, introduced in 1869. A dose of 0.3 Gm. of chloral hydrate given two or three times daily produces satisfactory sedative effects, and a similar dose or a somewhat larger one, up to 0.5 or 1 Gm., taken at bedtime, is a fairly satisfactory hypnotic. It is absorbed fairly rapidly, so that effects appear within fifteen or twenty minutes and last from six to eight hours. Chloral has a reputation for depressing the blood pressure and the circulation. Indeed, anesthetic doses of chloral hydrate in animals produce a type of effect upon the heart which is similar to chloroform. For example, if a cat is incompletely anesthetized with chloral hydrate, a slight struggle not infrequently causes a sudden cessation of the heart beat with ventricular fibrillation. Prolonged use of large doses of chloral hydrate also causes injury of the liver in a manner similar to chloroform. Such effects, however, do not apply

to the sedative or hypnotic doses of the order of 0.3 or 1 Gm., and I am unable to find any satisfactory reason for the prevailing belief that chloral hydrate in doses of the foregoing order should be withheld from patients with heart disease.

I am also unable to find any reason for the increasing interest in chloral hydrate. It is a strong irritant, sufficiently strong to cause blistering of the skin. It cannot be given in the convenient form of tablets or capsules. It has an unpleasant taste. These may be regarded as advantages or disadvantages, depending upon the point of view. The tendency to continue its use in a careless manner is less likely in the case of a medicine that has to be put into a solution and which has a disagreeable taste than in the case of an agent such as a barbiturate which can be taken in a convenient tablet form. I think everyone should treat himself to a taste of the ordinary 10 per cent solution of chloral hydrate dissolved in water or peppermint water. To me it seems much like drinking a dose of a liniment. The taste can be masked more effectively, but in any case the teaspoonful dose should be well diluted with water.

Paraldehyde is reputed to be one of the safest of the depressants and relatively free of a depressant action on the circulation. I am not sure that we have any evidence that it is any safer than the short-acting barbiturates. Of course, we see fewer deaths from it than from the barbiturates, but may not that be due to the fact that paraldehyde is used so infrequently? In a recent report of deaths from sedative drugs covering a ten-year period in Massachusetts, paraldehyde accounted for 8 of the deaths and barbiturates for 152.

Paraldehyde is fairly rapidly absorbed from the gastrointestinal tract, marked effects being in evidence in ten minutes or less. It is also rapidly eliminated, recovery taking place within two to four hours after such a large dose as 20 cc. given orally, a dose that causes such a degree of narcosis that a patient in labor may not be aroused during a pain. Like other depressant agents, there is, in the case of paraldehyde, fairly marked individual variation in susceptibility, and a dose of 25 cc. has been known to cause death in one, while others have recovered from a dose of 150 cc. A dose of about a teaspoonful given orally or by rectum produces fairly deep sleep. It has recently been used by intravenous injection in doses of 1 cc. of the undiluted material to control convulsive states. Its tendency to decompose, especially when exposed to sunlight,

should be borne in mind. The decomposition gives rise to acetaldehyde, which is extremely irritant.

Dr. Cattell made reference to the short-acting barbiturates. This development is of considerable importance. Phenobarbital causes anesthesia lasting for twenty-four to forty-eight hours; amytal, eight hours; pentobarbital, two hours; and evipal, only thirty minutes. Some depressant effects of such large doses, however, last much longer, so that these may still be in evidence for as long as five or six days in the case of phenobarbital and as long as twenty-four to thirty-six hours in the case of pentobarbital. A patient who is resistant to the hypnotic effects of these compounds and requires a fairly large dose, say 2 to 3 grains of phenobarbital, to induce sleep is apt to be better off if, instead of phenobarbital, pentobarbital is used, especially if the doses have to be repeated every day for a period. The short-acting barbiturate is less apt to produce the so-called "hangover," drowsiness, and stupor the following day and is less apt to show cumulative depressant effects if it is used for several days. This constitutes an advantage or a disadvantage, depending upon the objective. I think we ought to stress the point that the short-acting barbiturates are not entirely free of the hangover symptoms, and a dose of 3 grains of pentobarbital sodium, such as is commonly used for hypnotic effects, not infrequently produces a state of mental dullness on the following day.

Pentobarbital sodium is destroyed for the most part probably by the liver. Barbitol is eliminated chiefly by the kidney. Phenobarbital is eliminated by both mechanisms, the largest part of it usually being destroyed. Experimental studies show that animals recover with difficulty from some of the short-acting barbiturates in the presence of severe hepatitis, whereas they recover with difficulty from barbitol in the presence of experimental nephritis. These facts suggest a basis for selection in their therapeutic use.

Another matter concerning the short-acting barbiturates: After entering the circulation their maximum action develops rapidly. An anesthetic dose, for example, will produce anesthesia if injected intravenously within a half a minute or a minute. In the case of barbitol, however, the action develops slowly even after the material has entered the circulation, so that an anesthetic dose will take as long as a half hour or longer to produce anesthesia. These facts suggest an advantage in

the short-acting barbiturates, but the phenomenon has not been studied in man.

A point that is not always understood is the difference between barbitol or phenobarbital and their sodium salts. The sodium salt of the barbiturates is soluble, whereas the acid form is not. Some barbiturates are provided in the market only in their soluble forms. The soluble forms are, on the whole, better absorbed. The soluble forms are suitable for intravenous injection. The solutions are strongly alkaline and are too irritant for subcutaneous or intramuscular injection as a rule. An exception to this is phenobarbital sodium, which is only slightly alkaline and which can be given satisfactorily by subcutaneous or intramuscular injection. The long-chain barbiturates are not very stable in solution and, therefore, are provided usually in ampules containing the salt to be made up into a solution at the time of its administration.

Perhaps one reason why chloral and paraldehyde should be more frequently used than they are at the present time is that the likelihood of their leading to addiction is less. In general, patients are not prone to continue them longer than they can help. Chloral hydrate possesses a frightful taste and paraldehyde a frightful smell. There are, of course, patients with exceptional tastes—those who have no objection to either chloral or paraldehyde. The convenient tablet form in which the barbiturates are put up has probably something to do with the wide prevalence of their use. In patients with potentially addictive personalities, the placing at their disposal of a medication in such a convenient form, and one that can often be secured without the physician's prescription, is a source of real danger. There is a report from a psychopathic hospital in Missouri to the effect that one out of every ten psychoses was due to barbiturates. There is no evidence that the barbiturates possess any special addictive properties not applicable to other sedatives. The frequent addiction to the barbiturates seems to be related merely to the fact that they are available in a convenient form and used over long periods of time in an indiscriminate manner.

Perhaps doctors contribute a good deal to this abuse because of the general practice of prescribing phenobarbital for want of something to prescribe.

DR. CATTELL: We should like to have a few comments in regard to the use of sedatives in psychiatric patients and will call on Dr. Doty.

of the conferences last year. When Dr. Wolff was asked why he used phenobarbital in epilepsy to the exclusion of other barbiturates, he replied that it is the one that he and others had had the most experience with and that it had given satisfactory results, but he suggested that there are probably others equally good. It may, thus, be a matter of tradition which gives preference to the long-established drug, and it is not necessarily indicative of any real advantage of one barbiturate over another.

I imagine the increasing use of sodium pentobarbital is connected with the fact that it is representative of the short-acting barbiturates that have recently been developed. It is eliminated with much greater rapidity than amylal or barbital. I wonder if you would discuss this matter further, Dr. Gold?

DR. GOLD: In regard to Dr. DuBois' question concerning the virtues of the combination of chloral and bromides, I do not believe that there is any satisfactory proof that the combination has any particular merits. Chloral is eliminated fairly rapidly and bromide slowly, so that any mixture containing both, if taken for a protracted period of time, results in progressive accumulation of bromides. The patient is then, by virtue of this difference in elimination, changing the doctor's prescription, since at the end of a week or two he is being affected not by the combination in the bottle but by the revised combination in the body, and this revision continues as the doses are continued.

There seems to be a tendency to revive interest in chloral hydrate, which was one of the first hypnotics of the methane series, introduced in 1869. A dose of 0.3 Gm. of chloral hydrate given two or three times daily produces satisfactory sedative effects, and a similar dose or a somewhat larger one, up to 0.5 or 1 Gm., taken at bedtime, is a fairly satisfactory hypnotic. It is absorbed fairly rapidly, so that effects appear within fifteen or twenty minutes and last from six to eight hours. Chloral has a reputation for depressing the blood pressure and the circulation. Indeed, anesthetic doses of chloral hydrate in animals produce a type of effect upon the heart which is similar to chloroform. For example, if a cat is incompletely anesthetized with chloral hydrate, a slight struggle not infrequently causes a sudden cessation of the heart beat with ventricular fibrillation. Prolonged use of large doses of chloral hydrate also causes injury of the liver in a manner similar to chloroform. Such effects, however, do not apply

to the sedative or hypnotic doses of the order of 0.3 or 1 Gm., and I am unable to find any satisfactory reason for the prevailing belief that chloral hydrate in doses of the foregoing order should be withheld from patients with heart disease.

I am also unable to find any reason for the increasing interest in chloral hydrate. It is a strong irritant, sufficiently strong to cause blistering of the skin. It cannot be given in the convenient form of tablets or capsules. It has an unpleasant taste. These may be regarded as advantages or disadvantages, depending upon the point of view. The tendency to continue its use in a careless manner is less likely in the case of a medicine that has to be put into a solution and which has a disagreeable taste than in the case of an agent such as a barbiturate which can be taken in a convenient tablet form. I think everyone should treat himself to a taste of the ordinary 10 per cent solution of chloral hydrate dissolved in water or peppermint water. To me it seems much like drinking a dose of a liniment. The taste can be masked more effectively, but in any case the teaspoonful dose should be well diluted with water.

Paraldehyde is reputed to be one of the safest of the depressants and relatively free of a depressant action on the circulation. I am not sure that we have any evidence that it is any safer than the short-acting barbiturates. Of course, we see fewer deaths from it than from the barbiturates, but may not that be due to the fact that paraldehyde is used so infrequently? In a recent report of deaths from sedative drugs covering a ten-year period in Massachusetts, paraldehyde accounted for 8 of the deaths and barbiturates for 152.

Paraldehyde is fairly rapidly absorbed from the gastrointestinal tract, marked effects being in evidence in ten minutes or less. It is also rapidly eliminated, recovery taking place within two to four hours after such a large dose as 20 cc. given orally, a dose that causes such a degree of narcosis that a patient in labor may not be aroused during a pain. Like other depressant agents, there is, in the case of paraldehyde, fairly marked individual variation in susceptibility, and a dose of 25 cc. has been known to cause death in one, while others have recovered from a dose of 150 cc. A dose of about a teaspoonful given orally or by rectum produces fairly deep sleep. It has recently been used by intravenous injection in doses of 1 cc. of the undiluted material to control convulsive states. Its tendency to decompose, especially when exposed to sunlight,

biturates, because aspirin does not, even in toxic doses, cause narcosis. It has a limited depressant action, but a great many do find aspirin an effective sedative.

Summary

DR. CATTELL: The conference on sedatives and hypnotics has not treated this subject exhaustively, but many points have been considered. Several questions have been raised and some have been answered. I may briefly review the more outstanding statements. The terms "sedative" and "hypnotic" do not describe drugs but effects. All the central depressants serve both purposes. The condition of the patient and circumstances of their use determine the effect. A small group of these materials meets all the needs. Sometimes one will produce desirable effects when another fails, although more often it is a matter of dosage, and there is a good deal of aimless shifting about from one to another without advantage. Some resistance to their hypnotic effects is developed upon continued daily use. Interruption for a few days restores the response. Many patients react unfavorably to all hypnotic agents. The same patient may react differently at different times. These defects are occasionally corrected by a change of preparation. There are many patients who do not secure sleep or rest from the action of these compounds. Even these can,

of course, be narcotized by large doses and thereby provide temporary rest for the patient and some relief for the attendants and physician. The value of this treatment must, however, be viewed in the light of the exaggerated unrest, weakness, protracted stupor, and confusional states that follow large and cumulative doses. The rapidly absorbed and rapidly eliminated compounds like pentobarbital sometimes produce satisfactory results not obtainable with compounds like phenobarbital which are slower in both respects, since in the former the peak effect is more intense and the duration less prolonged. In the discussion, special characteristics and uses of various members of the group—namely, the barbiturates, bromides, chloral, paraldehydes, and aspirin—received some attention. These depressants are used much too extensively, often for want of something else to prescribe. Habitual use establishes a form of addiction, a phenomenon that is fairly common for this group of drugs. Tradition seems to have played a large part in the choice of agents producing sedative and hypnotic effects. Testimony concerning the relative merits of the several members and their specific application is still based to a large extent upon rumor. Scientific clinical investigation has played much too small a part in the body of knowledge concerning this group of therapeutic agents.

POSTGRADUATE OBSTETRIC COURSES

Five postgraduate courses in obstetrics, each of four weeks' duration, will be offered at the Chicago Lying-in Hospital between January 12 and June 6, 1942. These are sponsored by the Illinois State Department of Health and the Children's Bureau of the U. S. Department of Labor.

The features of the program consist of observations on current managements of normal and abnormal states of the pregnant, parturient, and puerperal patient. Lectures, demonstrations, clinics, and other teaching means augment

the operating room and birth room observations and ward round discourses.

The course is run on a nonprofit basis. A deposit of \$25 is required on registration, \$10 of which is refunded at the completion of the course. All the members of the department participate in giving the courses.

Additional information and application blanks may be obtained by request from Postgraduate Course, Department of Obstetrics and Gynecology, 5848 Drexel Avenue, Chicago, Illinois.

FIFTY THOUSAND CHILDREN NEED SIGHT-SAVING CLASSES...

... according to Mrs. Winifred Hathaway, associate director of the National Society for the Prevention of Blindness. Such classes are now maintained in more than 200 cities, with an enrollment of about 9,000 boys and girls, but there are still around 41,000 who need these special educational facilities. The children are not segregated from their companions with normal

vision, for they attend all the classes except those requiring close eye work which is done in a separate room with special equipment.

According to Mrs. Hathaway, farsightedness is the most common visual defect among American school children, astigmatism is next, and nearsightedness is third. The beginning of the school year is a good time for the examination.

DR. EDWIN J. DORF: I might follow Dr. Wheeler's outline in listing the drugs and remarking on them.

During my experience in the psychiatric inpatient service we have not had such a great occasion to use phenobarbital. We find it does not provide the desired effects unless used in large doses. It probably has an effect in cases of psychoneurotic patients and that type of patient with tension where mild sedative measures are not sufficient to control the restlessness and tension. It also has been used in combating insomnia in senile patients. We have not used much pentobarbital in the past, though recently it has been used more. We have been interested in the quickness of response to this drug.

With regard to the barbiturate psychoses, we see these much less frequently than in 10 per cent of the admissions. In fact, I have heard it often remarked in the department that we see them very infrequently. We do occasionally see reactions where large amounts of amytal seem to be the basis of the difficulty in combination with other factors, such as diminished food and fluid intake.

Sodium amytal is thought to have a beneficial effect in the excited schizophrenic states. In some, the response is unsatisfactory. It seems to be related to the individual susceptibility.

I do not think that bromides are used so much as formerly, when it was quite a fashion in the state hospitals to use what one might term "heroic doses." These were often as high as 30 or 40 grains, three times a day for a week, especially in catatonic excitements. At the present I believe just as good results are being obtained from smaller doses. Bromides have another use in agitated depressions and so-called involution melancholias, often with sexual tension. It seems to act specifically in diminishing the sexual tension.

Chloral hydrate is not used much by us, although the chief of the department is not impressed with the effect that has been referred to for years—namely, that it is deleterious to the myocardium.

Barbital would come much higher in our list of frequency of usage. In the clinic it is used a great deal in the agitated depressed states of later life depressions and in panic reactions. Often the administration of $2\frac{1}{2}$ grain doses, three or four times a day, seems to have beneficial effects in decreasing tension and avoiding panic reactions in patients subject to terrifying auditory hallucinations.

Paraldehyde, Dr. DuBois will probably be

interested in noting, is still the sedative of choice in the alcoholic group. When sedation is required we resort first to prolonged baths and other measures. We tend to avoid using wet packs from the cardiovascular standpoint. When the baths fail to give the desired results, we often use paraldehyde, perhaps in somewhat larger doses than would be used on the medical service, tending to give doses beginning with 12 cc. and going up to 30 cc. We have also used it in excited patients of the manic or catatonic type who have had a great deal of hydrotherapy and where we wanted to try some other measures. It has been used in excited patients where it is dangerous to give them something into the muscles or intravenously. Sometimes in these excited states it is possible to give it to the patients by nasal tube, and it has been used quite a bit in the past in that fashion with no undesirable results. One recent patient was given this at intervals for over a year while in the hospital. We had plenty of opportunity to check the patient psychologically and physically after recovery, and no changes were found which could be attributed to its use over a long period of time and in large doses.

With regard to bromides, I am not able to give definite answers to the particular questions raised regarding their use in epileptics. At times the blood concentration of the bromide in epileptics, after one has used large doses, reaches 400 mg. per hundred cubic centimeters without neuropsychiatric disturbances other than perhaps lassitude, and then suddenly convulsions will reappear even before the drug is stopped. Then one may discontinue the bromides and resort to phenobarbital and the convulsions will stop again.

We still see a fair number of acute toxic psychoses due to the unwise use of bromides. There the different bromide levels found in the blood seem to reflect the varying susceptibilities of the patients.

DR. JANET TRAVELL: There is one drug not on that list which is quite widely, and perhaps indiscriminately, used, at least by the lay public, and that is aspirin. I wonder if Dr. Gold would say whether it has any basis for use as a sedative and hypnotic?

DR. GOLD: Aspirin has sedative action. Aspirin raises thresholds, as Dr. Wolff and his collaborators have shown, in very much the same way as most of the other compounds we have considered. All the analgesic agents exert some sedative effects, for example, acetanilid or phenacetin. It belongs to the group behaving like bromides rather than the bar-

1. Preparation for blackout, so that hospitals may continue essential services and handle casualties under blackout conditions.

2. Protection of personnel from flying glass.

3. Fire protection with particular reference to control of incendiary bombs.

4. Protection and clearance of basement. Establishment of basement operating rooms.

5. Mapping of utilities and provision for sectional control and auxiliary service.

6. Clearance and fireproofing of attic and provision of accessible entrances to attic and roof.

7. Provision of reserve stocks—beds, blankets, food, fuel, drugs and biologicals, surgical dressings, etc.

The Hospital as a Training Center

As a training center the hospital serves a vital role in the civilian defense program. It alone can train nurses and volunteer nurses' aides.

Hospitals are keenly aware of the present deficiency in the supply of trained nurses. It is essential, for the protection of the public, that hospitals with training schools step up their production to the full limit of their resources. A recent hurry-up survey of hospitals by the New York State Health Preparedness Commission showed that approximately 10 per cent of available hospital staff positions were unfilled, due to inability of administrators to obtain properly qualified nurses. This was the state of affairs before the United States became involved in the War.

It is fully appreciated that the present needs cannot be met, or even partially met, with the speed now necessary, by accelerating the training of full-fledged nurses. For this reason the Office of Civilian Defense and the Red Cross, on

September 1, launched a program for the training of 100,000 volunteer nurses' aides—pinch hitters for wartime America.

Strict standards of selection of volunteers, intensive training, and a probationary extra-mural period are required in order to protect hospitals from defense dilettanti. Nurses' aides, working always under trained nurses, can carry a significant share of the hospital nursing load and can play an important community role by assisting in school, industrial, public health, and visiting nurse services. During enemy air attack they would be essential for the proper functioning of casualty stations and first-aid posts.

Internal Organization

So that smooth and efficient operation may be maintained under any conditions, plans must be made now for the reception of casualties. This must include plans for efficient distribution and routing of casualties to treatment, fracture, and operating rooms and to wards. Provision should be made for expansion of all of these facilities. Surgical teams, general and special, should be organized. Essential nonprofessional as well as professional personnel should be placed on call and priority of call established.

"Air Raid Protection of Hospitals," already distributed in preliminary form, will be available soon in final form as *Bulletin No. 3* of the Medical Division of the O.C.D. It includes suggestions on internal organization.

It is time now for hospitals to prepare themselves for any eventuality. No one knows whether the United States will be bombed. All that is known is that there are tremendous forces anxious to destroy our cities and our people.

That should be enough to stimulate action.

FOUR PHYSICIANS WHO MADE HISTORY

On a recent radio "quiz" program the question was asked, "How many signers of the Declaration of Independence were physicians?" It would be interesting to find out how many physicians know the answer. Well, here it is. There were four.

Dr. Lyman Hall, a graduate of Yale University in 1747, was ordained a minister and later practiced medicine in Connecticut, South Carolina, and Georgia. He was an ardent advocate of the Revolutionary cause and became a delegate to the Continental Congress. He was elected Governor of Georgia in 1783.

Dr. Benjamin Rush attended the College of New Jersey (now Princeton), graduating in 1760. He studied medicine under Dr. John Redman from 1761 to 1765, also attending the lectures of Dr. William Shippen and Dr. John Morgan in the College of Philadelphia and completing his medical education in Edinburgh in 1768. He returned to Philadelphia and began the practice of medicine. He became a member of the Continental Congress, and in April, 1777, was appointed Surgeon General of the Armies of the middle department. A member of the staff of the Pennsylvania Hospital, he established the first free dispensary in the country in 1786. He was Treasurer of the United States Mint from

1797 to 1813 but later devoted himself entirely to his practice and teaching.

Dr. Josiah Bartlett was born in 1729 and began the study of medicine at the age of 16 in the office of a distant relative, Dr. Ordway. Five years later he established a practice in New Hampshire. He was not only a physician but was active in public affairs, being elected Governor of New Hampshire and later Chief Justice of the Supreme Court of that state.

Dr. Matthew Thornton emigrated with his parents to America about 1718, settling first in Maine and later near Worcester, Massachusetts, where he studied medicine. In 1740 he began practicing in Londonderry, New Hampshire. Later he established his home in Connecticut. Giving up his professional practice, he became active in political affairs.

It is significant that few physicians today are outstanding figures in public affairs. At present there are only a handful of physicians in Congress, there being no Senators and less than a dozen Congressmen who are doctors of medicine. As has been emphasized by many who have commented on this subject in recent years, the country needs the public leadership which physicians are qualified to give.

Medical Preparedness

THE HOSPITAL IN CIVILIAN DEFENSE

H. VAN ZILE HYDE, M.D., Regional Medical Officer

Office of Civilian Defense, Second Civilian Defense Region

THE sudden advent of war, bringing with it a real threat to the civilian population of the United States, has impressed the hospitals of the country with the grave responsibilities they carry in relation to the protection of the public under attack from the air. The Medical Division of the U. S. Office of Civilian Defense published its recommendations concerning the establishment of Emergency Medical Service last August. Problems relating to blackout, protection of buildings, organization of emergency services, which seemed academic on Saturday, December 6, are now of immediate concern to every hospital administrator and to every physician. This sudden change in the status of these problems demands rapid orientation on the part of responsible hospital officials in matters relating to civilian defense and the hospital's part therein.

The hospital must integrate its services into the civilian defense mechanism of the community which it serves; assume responsibility for the proper protection of its own property; serve as a training center; and develop effective internal organization for the handling of casualties.

Integration with Civilian Defense Organization

In order that casualties occurring unexpectedly, often in large numbers and under chaotic conditions, may be promptly and properly handled with a minimum loss of life, hospitals must fit in with the complex mechanism which is being set up in all communities for the prompt delivery of necessary services to points of disaster. This mechanism consists of a system of control centers, each control center providing emergency services for a district. In each district control center there will be a civilian defense director or commander. With him there will be individuals responsible to him for each of the essential emergency services. In the control center a "medical adjutant" will represent the Chief of Emergency Medical Service and be responsible for the proper deployment of emergency medical field units, the establishment of casualty stations, first-aid posts and other medical emergency facilities. He will also keep the transport officer in the control center advised as to the need for ambulances and other transportation facilities required for the casualty services within the area. He will keep informed as to the number of available beds in the hospitals in the control area and will route casualties accordingly.

In large cities it will be necessary to have a main control center with all the facilities of the city at its disposal, in order to mobilize support for the control areas whose facilities are strained beyond their capacities. The main control center will keep informed through the District

Control Centers of the daily census of hospital beds available in all districts of the area and the status of all Emergency Medical Field Units and of all ambulances and other vehicles available in the various districts.

This control mechanism is being set up by the local authorities. To organize the casualty services, which are an essential part of the Emergency Services provided by the control mechanisms, Chiefs of Emergency Medical Service have been appointed on a county or city basis. They have prepared or are preparing spot maps for use in the control centers. These maps show the size and location of hospitals, the sites where casualty stations can be set up, the size and location of Emergency Medical Field Units, and other information necessary for the proper functioning of the medical adjutant in the control center.

Through the Chief of Emergency Medical Service, each hospital can determine how it fits into the general plan of emergency service in its community. As a basic necessity, every hospital has been urgently requested to form, drill, and equip Emergency Medical Field Units as described in Bulletins Nos. 1 and 2 of the Medical Division of the Office of Civilian Defense. These units are the tools with which the medical adjutant must work in providing effective casualty service to the population in his district in time of need.

The Chief of Emergency Medical Service carries a heavy responsibility. He is advised by the County Health Preparedness Committee and assisted by the New York State Health Preparedness Commission and the U. S. Office of Civilian Defense. He is responsible to the local Defense Council.

Protection of Hospital Property

Complete protection of property against damage from enemy air attack is impossible. Certain important measures can be taken, however, to ward off attack and to limit damage caused by attack. The extent to which these measures are carried out by any hospital, must depend upon the strategic importance of the area in which it is located, the structural characteristics of the building, the resources of the hospital, and the foresight of its management. The American Hospital Association and the Medical Division of the U. S. Office of Civilian Defense, working together, have drawn up and issued recommendations concerning the "Air Raid Protection of Hospitals." Using this in conjunction with "Blackouts" and "Glass and Glass Substitutes," published by the Office of Civilian Defense, hospital administrators are in a position to proceed according to the requirements of their own areas. The matters to be taken under immediate consideration are:

Medical News

Dr. Moorhead on Active Duty in Honolulu

EVENTS have proved that the lecture committee of the Medical Society of Honolulu was keenly foresighted in inviting Dr. John J. Moorhead, of New York City, to deliver a series of lectures on traumatic surgery. Dr. and Mrs. Moorhead arrived in Honolulu but a few days before the treacherous Japanese, and, instead of lecturing, Dr. Moorhead, a lieutenant-colonel

in the Medical Reserve Corps, returned to active duty, according to a report published in the *New York Sun* on December 12.

Dr. Moorhead—an authority on traumatic surgery—is on the staff of New York, Post-Graduate Hospital as consulting surgeon and is on Governor Lehman's committee on civilian defense.

County News

Albany County

On December 10 the following officers were elected: president, Dr. John J. Phelan; vice-president, Dr. Morgan O. Barrett; secretary, Dr. Homer L. Nelms; treasurer, Dr. Frances E. Vosburgh; and historian, Dr. Emerson Kelly. Censors are: Dr. T. O. Gamble, Dr. E. S. Goodwin, Dr. J. B. Horner, Dr. R. G. Leddy, and Dr. E. W. Wilkins. Delegates are: Dr. Otto Faust, Dr. R. F. Kircher, and Dr. Homer L. Nelms. Alternate delegates are: Dr. William Feltman, Dr. J. L. Lochner, Jr., and Dr. Clarence Traver.

The Nominating Committee consisted of Dr. John E. Heslin, chairman; Dr. Arthur M. Dickinson; Dr. Thomas Tyrrell; Dr. James W. Bucci; and Dr. Earle W. Wilkins.—*Homer L. Nelms, Secretary.*

Broome County

At the annual election of the county society held December 9, the following officers were elected for the year 1942: president, Dr. Elton R. Dickson, Binghamton; vice-president, Dr. F. G. Moore, Endicott; secretary, Dr. H. Jackson King, Binghamton; assistant secretary, Dr. M. A. Carvalho, Binghamton; treasurer, Dr. C. H. M. Goodman, Binghamton; and assistant treasurer, Dr. G. T. Riley, Binghamton.

The chairmen of the committees are as follows: economics, Dr. C. J. Marshall, Binghamton; legislative, Dr. V. W. Bergstrom, Binghamton; library, Dr. S. B. Blakely, Binghamton; membership, Dr. R. J. McMahon, Johnson City; public health, Dr. W. J. Farrell, Johnson City; public relations, Dr. F. M. Dyer, Binghamton; and milk commission, Dr. P. B. Jenkins, Binghamton.

The Board of Censors are: Dr. S. D. Molyneaux, chairman, of Binghamton; Dr. C. H. Verlinghof, of Binghamton; Dr. J. J. Cunningham, of Binghamton; Dr. G. C. Hamilton, of Binghamton; and Dr. F. G. Moore, of Endicott.

The Compensation Board are: Dr. H. I. Johnston, of Binghamton; Dr. A. R. Carpenter, of Binghamton; Dr. D. C. Chamberlain, of Binghamton; and Dr. F. G. Moore, of Endicott.

Delegates are Dr. C. M. Allaben and Dr. C. L. Pope, of Binghamton; alternate delegates are Dr. S. M. Allerton and Dr. S. B. Blakely, of Binghamton.—*H. Jackson King, M.D., Secretary.*

Chemung County

New officers, elected at the annual meeting

on November 26 in Elmira, are: president, Dr. Leon C. Hamilton; vice-president, Dr. F. Sullivan Hassett; secretary, Dr. Harold L. Walker; treasurer, Dr. M. Frederick Butler.

Dr. William T. Boland, chairman of the Public Health Committee, recently announced that inoculation of every resident of Chemung County who has not already been immunized against diphtheria, smallpox, tetanus, typhoid fever, and whooping cough has been declared necessary by the county society.

The recommendation has been made because of the influx of workers in defense industries in the area, Dr. Boland said. A resolution on the program was adopted at the annual meeting of the Medical Association.

A "Maternal and Child Welfare Day" was conducted December 10, to afford physicians in this area an opportunity for postgraduate study. The program was presented under the auspices of the Maternal and Child Welfare committees of the Allegany, Steuben, Schuyler, Tompkins and Chemung county medical societies, the Arnot-Ogden Hospital, the Division of Maternity, Infancy and Child Hygiene of the New York State Department of Health, and the Medical Society of the State of New York.

Clinton County

The annual fall meeting of the county society was held on November 25. The following officers were elected for the incoming year: president, Dr. Dana Weeks, Peru; vice-president, Dr. Leonard Schiff, Plattsburg; secretary, Dr. James J. Reardon, Plattsburg; treasurer, Dr. K. M. Clough, Plattsburg; censors, Drs. Elme Wessell, Sidney Mitchell, and William W. Johnson, all of Plattsburg.—*James J. Reardon, M.D., Secretary.*

Delaware County

The December meeting of the Society was held in Delhi on December 16 at the Elm Tree Restaurant.

Dr. Stuart B. Blakely, of Binghamton, presented to the society "An Analysis of Four Maternal Deaths."—*O. Q. Flint, Secretary.*

Dutchess County

A regular meeting of the county society was held on December 10 at the Amrita Club in Poughkeepsie.

Cancer Teaching Day—Syracuse

The Cancer Teaching Day, presented under the auspices of the Tumor Clinic Association of the State of New York, the Syracuse University College of Medicine, the Medical Society of the State of New York, and the Division of Cancer Control of the New York State Department of Health, will be held at the Syracuse University College of Medicine, 766 Irving Avenue, Syracuse, New York, on Saturday, January 17, 1942.

Program

The Syracuse meeting called to order at 1:30 P.M.

Opening remarks: HERMAN A. WEISKOTTEN, M.D., Dean, Syracuse University College of Medicine.

Chairman of the meeting: FREDERICK S. WETHERELL, M.D., President, Tumor Clinic Association of the State of New York.

"The Role of Tumor Clinics in Cancer Control," BOWMAN S. CROWELL, M.D., Associate Director, American College of Surgeons, Chicago. Discussion: LOUIS C. KRESS, M.D., Director, Division of Cancer Control, State Department of Health, Albany, New York.

"The General Practitioner and the Diagnosis of Cancer," LLOYD F. CRAVER, M.D., Attending Physician, Memorial Hospital, New York City. Discussion: KARL F. ESCHELMAN, M.D., Director, Tumor Clinic, Edward J. Meyer Memorial Hospital, Buffalo, New York.

"Advances in Surgical Treatment of Cancer," JOHN J. MORTON, JR., M.D., Professor of Surgery, University of Rochester School of Medicine, Rochester, New York. Discussion: GEORGE W. CURTIS, M.D., President-Elect, Medical Society of the State of New York, Jamestown, New York.

"Biopsy—Indications and Methods," J. HOWARD FERGUSON, M.D., Associate Professor of Pathology, Syracuse University, College of Medicine, Syracuse, New York. Discussion: RUDOLPH J. SHAFER, M.D., Pathologist, Corning Hospital, Corning, New York.

Dinner Meeting

6:15 P.M. Small Ballroom, Hotel Syracuse, Syracuse, New York.

Chairman of the meeting: O. W. H. MITCHELL, M.D., Syracuse, New York.

Opening remarks: EDWARD S. GODFREY, JR.,

M.D., Commissioner, New York State Department of Health.

"Principles of Radium and X-Ray Therapy," G. ALLEN ROBINSON, M.D., Director, Tumor Clinic, Flower and Fifth Avenue Hospitals, New York City; WALTER T. MURPHY, M.D., Radiologist, State Institute for the Study of Malignant Diseases, Buffalo, New York.

"X-Ray as a Diagnostic Aid in Cancer," BYRL R. KIRKLIN, M.D., Chief, Section on Radiology, Mayo Clinic, Rochester, Minnesota.

Local Committee on Arrangements

Leo E. Gibson, M.D., *Chairman*

Wardner D. Ayer, M.D.

Donald S. Childs, M.D.

Arthur N. Curtiss, M.D.

James G. Derr, M.D.

H. Burton Doust, M.D.

Richard S. Farr, M.D.

J. Howard Ferguson, M.D.

Leon H. Griggs, M.D.

Lee A. Hadley, M.D.

Louis M. Hickernell, M.D.

Gordon D. Hoople, M.D.

All physicians in the state are cordially invited. The price of the dinner is \$2.00. No other fees will be charged. Dress: informal. The sponsoring agencies are anxious to know how many will attend the afternoon session and how many the dinner meeting. Reservations should be addressed to: O. W. H. Mitchell, M.D., *Chairman*, Council Committee on Public Health and Education, Medical Society State of New York, 428 Greenwood Place, Syracuse, New York.

JOURNAL OF THE NEW YORK COUNTY MEDICAL SOCIETY

Beginning January 3, 1942, the *Journal of the Medical Society of the County of New York* will make its appearance, replacing the *New York Medical Week*, which for many years has been

the official publication of the society. The new *Journal* will have a larger format, and the offices will be located at 2 East 103rd Street, New York City.

"I FEEL LIKE A
NEW WOMAN!"

A clear case of Ivory's new mildness!

For a baby's skin—or just for the joy of bathing—New "Velvet-Suds" Ivory Soap is better than ever! It gives the quickest, creamiest lather that ever foamed off a cake of Ivory—and it's actually milder.

Ivory's uniformly high standard of mildness is far superior to that of imported olive oil castiles. In fact, a recent examination of imported castiles showed that 42 out of 44 examples showed definite evidence of rancidity—an irritating factor.

Ivory is uniformly mild—milder than 10 leading toilet soaps by test, milder than any other widely advertised floating soap. No

dye, medication, or strong perfume that might be irritating. You can advise new improved Ivory with confidence.

FREE—for your use in maternity cases, a 16-page illustrated booklet "*Bathing Your Baby The Right Way.*" The technique described is approved by the Maternity Center Association of New York. It covers correct methods of handling baby, equipment, and a step-by-step outline of the bath. We will gladly send you a free copy with order blank for additional copies. Simply send postcard to Procter & Gamble, Dept. N, Box 687, Cincinnati, Ohio.

PROCTER & GAMBLE • TRADEMARK REG. U. S. PAT. OFF.

On the program was Dr. Scott Lord Smith, F.A.C.P., attending physician at Vassar Brothers Hospital, Poughkeepsie. His subject was "Sulfonamides and Related Compounds."

Erie County

At the Buffalo Academy of Medicine on December 3 Dr. Samuel C. Harvey, professor of surgery, Yale University, spoke on "Problems of Wound Healing." Dr. Herbert A. Smith and Dr. Hoyt E. DeKleine led the discussion.

Dr. Philip W. Brown of the Mayo Foundation, University of Minnesota, talked on "Diagnosis and Treatment of Diarrhea" on December 10.

"The times require nonobstructive organization among physicians," Dr. George W. Cottis, of Jamestown, president-elect of the Medical Society of the State of New York, told members of the Medical Society of Erie County at the November meeting.

He asserted that the chief function of an organized society is to get together, formulate wise policies, and then put them over. He pointed out that social and economic changes are being accelerated at a tremendous rate.

Discussion Important

"Our own traditions and the laws of the state require that we shall be responsible to individuals," he said. "We must retain our individualistic traditions and not obstruct every change that is bound to come. There never has been a time so important that we get together and discuss the problems facing us. The purpose of debate is to iron out differences and determine what we should do.

"It is time that we took the offensive, listened to our best brains, adopted policies and then put them over. Already we are being governed largely by groups. The government is being changed from a legislative government to an executive government by groups. Our paramount interest is to see that when that day comes, we are our own managers."

Greene County

Public opinion won a victory in Greene County on November 10, according to the S.C.A.A. Bulletin, when the Board of Supervisors authorized an appropriation of \$7,118 for the employment of three county public health nurses. State aid will return to the county one-half of this expense, and the State Health Department has promised the services of two additional nurses, making five in all.

Behind the accomplishment is a classic example of resourcefulness, planning, persistence, and teamwork exercised by the Greene County Tuberculosis and Public Health Association.

Greene County, population 23,191, with Catskill the largest community, discontinued its nursing services early in the depression. In 1938 it was one of the fourteen counties selected for intensive promotion of public health nursing by the State Health Department and the S.C.A.A. State Committee on Tuberculosis and Public Health. No county appropriation was secured, but this effort resulted in the County Association employing an executive secretary, Mrs. Frederick C. Fiero, who, with assistance from the District Office of the State Health Department

and the State Committee staff, launched a campaign of public education on the need for nursing service in the county.

Herkimer County

The 135th annual meeting of the county society was held in the parish hall of Christ Episcopal Church in Herkimer on December 9, at 4:00 P.M.

The scientific program included an address by the president, Dr. H. D. Vickers, Little Falls, and a paper, "History of Ophthalmology," by Dr. D. F. Aloisio, Herkimer. The annual reports of other officers were given, and officers for 1942 were named.

The annual banquet was served at 6:00 P.M.

Jefferson County

The regular monthly meeting of the county society was held on December 11 at the Black River Valley Club in Watertown. Dinner preceded the program, which consisted of an address on "The Management of Gastrointestinal Bleeding," by Dr. Lawrence A. Kohn, associate in medicine at Strong Memorial Hospital, Rochester.

Kings County

At the first annual dinner to ex-presidents of the county society and the Academy of Medicine of Brooklyn to be held on January 17 at the Hotel St. George, Brooklyn, Colonel Samuel J. Kopetzky, president of the State Medical Society, will present the medals and scrolls. Speakers announced are Mayor La Guardia and Dr. Morris Fishbein.

At the regular meeting on December 16 Dr. William R. Cubbins, of Chicago, spoke on "Injuries About the Knee Joint." Officers were elected at this meeting and will be printed in the next issue.

At the annual meeting of the Brooklyn Urological Society, the following officers were elected: president, Dr. James W. McManus; vice-president, Dr. Samuel E. Last; and secretary-treasurer, Dr. John J. Bottone.

Livingston County

Dr. Kenneth T. Rowe, of Dansville, spoke on "Common Problems of Urology at the meeting held on December 10 at the LaDelfa Hotel, Mt. Morris. The woman's auxiliary held a separate meeting at the same time.

Monroe County

On December 16 the annual meeting of the county society was held in Rochester. Dr. Morris Fishbein, the speaker of the evening, was honored at a dinner preceding the meeting.

Dr. Frank H. Lahey, director of the Lahey Clinic and president of the A.M.A., addressed the Rochester Academy of Medicine on December 2. The subject of Dr. Lahey's talk was "Cancer of the Colon and Rectum." Reporting a series of 1,200 cases, Dr. Lahey drew his deductions in an interesting way for the general practitioner.

A dinner before the meeting was given at the Country Club for Dr. Lahey.

Montgomery County

At the annual meeting of the county society the following officers were elected for 1942: president, Dr. James M. Bernhard; vice-president, Dr. William Bing; secretary, Dr. Roger Conant; treasurer, Dr. Leonard M. McGuigan; delegate to the State Society, Dr. Robert C. Simpson; alternate, Dr. P. J. Fitzgibbons; delegate to the Fourth District Branch, Dr. Charles E. Slater. With the exception of Dr. Slater, who is from Fort Plain, all the officers live in Amsterdam. —*Roger Conant, M.D., Secretary.*

New York County

The following letter was recently printed in the *Medical Week*:

"Editor, Public Forum: The editorial appearing in the current issue of *Medical Week* discussing the various voluntary health care plans in operation is excellent. As you know, my particular interest is that such statements should be made as that which you make on page 5: ' . . . it is undoubtedly to the interest of the profession and the community as a whole that there be experimentation along various lines.'"

"There is one implication in your editorial, however, which I think is unintentional, namely, that a physician must choose between the Medical Expense Fund of New York and Group Health Cooperative, and that enrollment in one precludes participation in the other. This, of course, is not the case. Physicians can operate under both plans without any complications, and I am sure that there are a good many physicians in New York who would like to have this matter cleared up for them.

KINGSLEY ROBERTS, M.D., *Chairman,*
Medical Advisory Board"

1790 Broadway,
November 25, 1941

At the monthly meeting on December 22 Dr. Leona Baumgartner spoke on "School Health Program and the Private Physician." Mr. John Splain, Metropolitan director, Safety-Responsibility, spoke on the Safety Responsibility Act. Dr. Miles Atkinson had as his subject "Medicine as a Social Science."

Onondaga County

The following officers were elected at the annual meeting of the county society held in Syracuse on December 2: president, Dr. Ambrose T. Lawless; vice-president, Dr. Herbert C. Yeckel; secretary, Dr. Dwight V. Needham (re-elected); treasurer, Dr. A. Carl Hofmann (re-elected); delegate to State Society (3-year term), Dr. A. G. Swift; alternate delegate to State Society (3-year term), Dr. D. S. Childs; and delegates to Fifth District Branch, Dr. F. G. Dye, Dr. W. O. Kopel, Dr. M. A. Obremski, and Dr. M. S. Richards.—*Dwight V. Needham, M.D., Secretary.*

Rockland County

Dr. E. Armand Scala, of Suffern, was elected president of the Rockland County Medical Society at its annual meeting and dinner at the Villa Lafayette in Spring Valley on December 3.

Vice-president is Dr. E. Hall Kline, of Nyack, and Dr. Dean Miltimore was re-elected once more

after a full quarter-century of service as treasurer. Another perennial of long standing is Dr. William J. Ryan, of Pomona, who will once more be secretary. Dr. Matthew J. Sullivan, of Haverstraw in a short address marking his retirement, paid high tribute to the service Dr. Miltimore and Dr. Ryan have rendered the society.

Dr. F. B. Theis, of Nyack, was made chairman of the membership committee (Dr. Miltimore announced there were 100 members in good standing), and Dr. Russell E. Blaisdell, of Orangeburg, is chairman of the legislative committee Dr. Frederick A. Schroeder, of Pearl River, is chairman of the public health and public relations committee, with Dr. Alfred S. Moscarella, of Spring Valley, as cochairman. Dr. Harold S. Heller, of Spring Valley, is chairman of the committee on medical economics, with Dr. Frank E. Ciancimino, of Nyack, as cochairman.

Elected to the Board of Censors for two years, with the exception of the vice-chairman, are Dr. George M. Richards as chairman, Dr. Sullivan as vice-chairman, Dr. George G. Stone, Dr. John C. Dingman, Dr. Royal F. Sengstacken, and Dr. Edwin O'Dowd. The delegate to the State Medical Society for 1942-1943 is Dr. Stephen R. Monteith, with Dr. Ryan as alternate.

Introduced were Dr. Terry Townsend, a former president of the State Medical Society, Assemblyman Robert Doscher, and Dr. S. W. S. Toms, of Nyack, in whose honor the county society held a dinner on December 11 at the Hotel St. George in Nyack in observance of his fifty years of active practice. Dr. Toms was eighty on that date.

Speakers of the evening were Dr. F. R. Strutton of the State Hospital, Dr. Leon H. Goldberg, of Nyack, and Roland Logan, trainer for varsity athletics at the West Point Military Academy. Mr. Logan mingled sparkling Irish wit, oratory, and song with experience in his long career of training athletes.

Schenectady County

Judging from the picture of the "Calomelodians" in the *Bulletin* and the *Schenectady Gazette* there isn't much difference between, say, Glen Miller's boys and Glen Smith's, for the society orchestra certainly has that unmistakable professional look.

The orchestra was organized in February, 1940, and its members rightfully feel that it serves a double purpose: "Besides providing entertainment and amusement, an enterprise of this sort is one of the best influences to maintain a solid, wholesome spirit of congenial fellowship among the entire medical society."

Members of the orchestra, in addition to Dr. Smith, conductor, are Drs. C. F. Ackerknecht, Philip Parillo, Nelson H. Rust, William M. Mallia, F. H. Pulver, Gomer Richards, H. W. Galster, R. L. Faulkner, Raymond H. Warner, J. H. Kalteux, R. J. Hotchkiss, E. G. St. John, Michael Slovak, J. J. York, R. C. Maxon, C. L. Moravec, G. A. Reich, S. F. MacMillan, D. K. Binder, August B. Korkosz, and H. E. Reynolds.

At the annual meeting at the Mohawk Golf Club in Schenectady on December 4 the Doctors' Orchestra played several selections. The speaker of the evening was Charles John Stevenson, editor of the *Washington County Post*. His sub-

...THE BRAIN

When electroencephalography records the brain potential of epileptic patients prior to and after the use of Kapseals Dilantin Sodium, the oscillograph usually depicts more normal brain waves. Furthermore, seizures diminish in frequency and severity. As a result of this, the patient's general attitude and behavior are favorably influenced and he is permitted to enjoy a more normal life.

A combined report of thirteen clinicians states that in 404 out of 595 epileptic patients, Dilantin Sodium was more effective than other anti-convulsants¹. Its value in patients not responding to other medication has been reported². All in all, Dilantin Sodium (phenytoin sodium), a product of long and systematic research in clinic and laboratory, marks a definite forward step in the management of epilepsy. Complete details upon request.

ject was "Practicing Medicine for Pleasure." A movie in technicolor, "The Bull Fight," was shown by Dr. Arthur "Quistador" Penta.

At this meeting Dr. Joseph H. Cornell was elected president of the county society; Dr. William F. Nealon, vice-president; and Dr. Gomer Richards, secretary.

Other officers selected were Dr. Raymond H. Warner, treasurer; Dr. Cornell, delegate to the house of delegates of the State Society, with Dr. James Smith as alternate.

Tioga County

The annual meeting of the county society was held on December 2 at the Green Lantern Inn in Owego. The election of officers followed a dinner served at 6:30. The nominees, all elected, were published November 1.

The speaker at the meeting was Dr. S. B. Blakely, of Binghamton, who spoke on the subject, "Maternal Mortality." A discussion of the subject followed the talk.

Tompkins County

The county society held its annual meeting December 9, at Willard Straight Hall, Ithaca. A steak dinner preceded. Professor Syman P. Wilson of Cornell Law College gave a most interesting talk on "A Lawyer Looks at the Doctors."

The following officers, all from Ithaca, were elected: president, Dr. Dean F. Smiley; vice-president, Dr. Henry W. Ferres; secretary-treasurer, Dr. Willets Wilson; censors, Drs. Richmond Douglass, Arthur B. Berresford, Leo P. Larkin, Henry B. Sutton, Philip J. Robinson; delegate, Dr. Leo P. Larkin; and alternate, Dr. Dean F. Smiley.—*Willets Wilson, M.D., Secretary.*

Ulster County

The county society has told the Board of Supervisors that the doctors are all through handling relief and old-age medical and surgical cases without pay and asked that a committee of the

board meet with a committee of the society to set rates of pay for this service.

The doctors' point of view was presented by Dr. Virgil B. DeWitt, of New Paltz, chairman of a committee named some months ago by Dr. John B. Krom, of Kingston, president of the county society, to study the matter. Other members of the committee were Dr. Alfred M. Feldshuh, of Kerhonkson, Dr. William S. Bush, of Kingston, and Dr. Eugene F. Galvin, of Rosendale.

Dr. DeWitt said that there is no present arrangement for payment of the medical or surgical care for the relief cases, those on old-age pensions, and the blind, while other counties have a standard fee system for paying the doctors. He stated that he was not asking the county to pay the same rates for these cases that are paid by individuals, but he thought that a systematized payment should be made such as is in force in Orange, Nassau, Rockland, Yates, and other counties.

Westchester County

Dr. George C. Adie, in a presidential address on November 18, spoke thus of the functions of a society:

"All through the history of medicine quarrels and disagreements between the various cults and branches of the healing art have existed until now there seems to be no great divergence of opinion in broad principles. It may have been good for the progress of medicine to have these quarrels, but in this day and age and in this community where we all practice the same kind of medicine there is no room for prejudice, jealousies, and factions.

"The local society should function with the idea of making the smaller group cohesive, while the County Society can do much to cement the component parts together in a unified, friendly, and harmonious group. It should promote the welfare of the physician, keep his scientific attitude stimulated, and create a spirit of comradeship."

NEW YORK STATE JOURNAL OF MEDICINE

Copyright 1942 by the Medical Society of the State of New York

VOLUME 42

JANUARY 15, 1942

NUMBER 2

Editorial

A Call to Service

The rapidly increasing need for medical personnel in the war will be met by the new Procurement and Assignment Service for Physicians, Dentists, and Veterinarians according to the *J.A.M.A.* for December 27, 1941, and January 3, 1942.

(See Medical Preparedness, page 175.)

The P. and A. Service will shortly publish, through the *J.A.M.A.* and in these pages, a tabulation of the physical requirements for physicians applying to any of the federal services.

What's the Idea?

The armed forces need medical men, dentists, and veterinarians at once—lots of them. A pool of physicians must be available from which applicants for commissions might be drawn promptly. The *J.A.M.A.* for the past two issues carried a tear-out sheet which some of you may

have seen. It was an application form for a commission. Some of you may have filled it out and sent it in.

If you have not, here is your second chance. Tear out the sheet on page 121 of this issue, fill it out, send it to Dr. Sam F. Seeley (address on form).

Now

The immediate needs of the Army are for men in the grades of lieutenant and captain. This applies particularly to men under 45. Never mind what other

questionnaires you may have filled out previously. This is urgent and serious business. Do this at once. It may save you endless trouble.

Why?

Because the age limits of Selective Service have been extended, older men will shortly have to register for service with their local draft boards. Medical men who have filled out and returned the questionnaire will already have applied for a commissioned status. They will not have to serve as enlisted men.

Those physicians desiring to refer to the complete plans for handling profes-

sional personnel in war or to inform themselves more fully about the function of Procurement and Assignment Service and the names of committeemen announced for the various corps areas will turn to page 175 for this information.

Let us repeat. If you have not filled out the blank application form in the *J.A.M.A.* for December 27, 1941, fill out the facsimile on page 121 of this Journal.

Turn to Pages 121-122—*At Once*

Read Carefully

The Editors of this JOURNAL have frequently urged the membership of the Society to read the issues carefully.

We urge it again. We know that some do not receive the *J.A.M.A.*; others do not attend their county meetings regularly, still others not at all. All members of the Society receive this JOURNAL. We endeavor to publish and republish important announcements which concern the medical profession in the state.

Because this JOURNAL appears twice a month, the membership is fortunate in that important notices and bulletins can

be brought to its attention at a date in advance of most other publications except the *J.A.M.A.*

Now that we are at war, it becomes more than ever necessary that this JOURNAL be read carefully, especially by those members who do not receive the *J.A.M.A.* Your Editors will endeavor to keep you up to date on all things relating to the profession at war as well as the affairs of your respective localities as reported to us by your county societies. We ask again that you read promptly and carefully.

Correspondence

"War and the Woman Physician"

To the Editor:

I wish to address the Men Physicians of New York State through your column.

It has been my proud privilege to be a member of the House of Delegates in the Medical Society of the State of New York for about a decade.

During this time I have seen much forward-looking legislation transacted. Possibly no one act has commanded my respect more than when the House went unanimously on record as recommending that women physicians be admitted unreservedly to the Medical Reserve Corps of the United States Army and Navy. This was an act of modern gallantry on the part of the men to their sister women physicians. Yes, it was this and a great deal more, for it was a declaration of justice for women that they should have equal rights with men physicians where these rights had been earned.

The fact that this momentous recommendation from the House of Delegates was not ratified by the higher Medical Tribunal in no way dims the splendid act of the Empire State taking its stand for its women physicians, the first of any state to do so. The women physicians of New York State have been heartened and thrilled by your act and extend to you all deep gratitude and appreciation.

Another war is upon us and grim days are ahead. As President of the American Medical Women's Association, I have found that my most important duty has been to find out where the woman physician fits into the picture of World War No. II.

In tracing down all the illusive reasons why women physicians are ineligible to the Medical Reserve Corps, and the hints of necessary legislation to bring this about, I have at last been able to get some basic facts.

They are as follows: (1) Women physicians are eligible to the Medical Reserve Corps of the United States Army. (2) Women physicians are ineligible to the Medical Reserve Corps of the Navy, but this ineligibility could be removed by the Navy if and when they might consider it expedient to admit women. These facts come directly from the headquarters of the Army and Navy.

Acting on this information, the following resolution was duly adopted at the Mid-Year Board Meeting of the Directors of the American Medical Women's Association held at the Women's Medical College of Pennsylvania on Saturday, December 6, 1941:

WHEREAS, There has been no change in respect to military rating for women physicians since the first World War; and in our present state of war preparedness women physicians now find themselves in an anomalous and undignified position as compared with nurses who now have full military rating with all the privileges thereof; and

WHEREAS, During the period between World War No. I and World War No. II, women physicians have taken advantage in ever increasing numbers of their enlarging opportunities for broader professional training, due to the fact that

large medical schools and hospitals are now open to them, they are now admitted to the most important medical societies, are Fellows of the American College of Surgeons and College of Physicians and are holding positions of trust and responsibility on hospital staffs, college boards, and departments of health all over the country; and

WHEREAS, The bulk of our practicing women physicians are in a position economically and socially to qualify for work in Civilian Defense in case of national emergency; and

WHEREAS, There is also a small but very important percentage of practicing women physicians in the proper decades of life, unattached, in good health, well-trained and desirous of seeing active service for the same reasons that their equally well-trained male colleagues are; among these women being experts in the fields of medicine, surgery, anaesthesia, bacteriology and pathology, and in the specialties of neuropsychiatry and of eye, ear, nose, throat, and skin diseases, whose services would be of great value in base hospitals and wherever military nurses are sent; and

WHEREAS, Many of the best of the women physicians in this preferred qualification group, having received no recognition whatever from our government, are accepting positions for professional work in England and we are losing our very best women physicians in this way; and

WHEREAS, Both the Army and the Navy of the United States of America have repeatedly publicized the fact that there is a serious shortage of physicians in the Medical Reserve Corps, the shortage being estimated in the thousands; and

WHEREAS, The Houses of Delegates of the Medical Societies of New York and New Jersey have gone on record as being overwhelmingly in favor of making women physicians eligible for the Medical Reserve Corps, and

WHEREAS, The Medical Reserve Corps Act of the Army makes no sex discrimination whatever, the sole requirement being that applicants be citizens of the United States with the proper professional training; and

WHEREAS, The taxpayers are being called upon to furnish huge sums of money for the building and equipping of hospitals and other buildings for the medical care of the Army and the Navy; and now is the time, while such buildings are in process of erection, to provide suitable quarters for women physicians in all such buildings, base hospitals and other institutions where they may be assigned (lack of proper housing facilities being one of the arguments most commonly advanced as to why women physicians cannot be attached to hospital units); therefore be it

Resolved, That we the undersigned do hereby respectfully and earnestly request that women physicians be admitted to the Medical Reserve Corps of the United States Army upon the same terms as all the rest of its members and with all the privileges accorded thereto; and be it further

Resolved, That a copy of this resolution be forwarded to the President of the United States, to

the Secretary of War and to the Surgeon General of the Army.

Respectfully submitted,

American Medical Women's Association, Inc.,
By its

Officers
Regional Directors
Chairman of Standing Committees
Chairman of Special Committees

The resolution to the Navy is in all respects identical except paragraph 8, concerning the Medical Reserve Corps Act, which was deleted and the following paragraph inserted: "WHEREAS, The Medical Reserve Corps Act of the Army makes no sex discrimination whatever, the sole requirement being that applicants be citizens of the United States with the proper professional training, and the Navy Regulations which, unlike the Army Regulations, restrict service in the Medical Reserve Corps to men, thereby declaring women ineligible, are easily susceptible of amendment by the proper authorities; and" and in the final paragraph the following was deleted "to the Secretary of War and Surgeon General of the Army" and the following inserted "to the Secretary of the Navy and to the Surgeon General of the Navy."

Why are women physicians not admitted to the Medical Reserve Corps of the United States Army, when they are eligible, and at a time when there is an advertised shortage of physicians in the Medical Reserve Corps of between 1,000 and 2,000?

It is because Surgeon General James C. Magee of the United States Army does not think that women should belong. In a recent fundamental talk with General Magee, he stated that this is his conviction and that he feels there are many places in civil life and in Civilian Defense where women physicians' services could be utilized to much better advantage than in the Army. When pressed further I asked him whether a Surgeon General could change his mind if convincing arguments could be brought to the fore? He intimated that this would not be impossible.

Are the women physicians willing to leave this issue which is of vital importance to them on this anomalous basis? No—they are unwilling to do so. They want to find themselves in a dignified position with sufficient rank and authority to do a good job. They want the same pay and privileges as their brother physicians, the same protection in case of sickness or injury and, if called upon to make the supreme sacrifice, to be assured that their dependents will have the same protection. The Army and Navy have protected their women nurses along these lines. Should the women physicians receive less consideration?

Women physicians are told that positions are awaiting them in civil life, home defense, and public health services, where they can fill in the gaps left by men doctors who have gone into the service.

It has been woman's privilege from time immemorial to do the men's home work when they are away fighting, that goes without saying, and women have never shirked it. This, however, does not cover the present case. Most of these home defense jobs are voluntary, and many women can take them on in addition to a practice which makes them self-supporting. But there is a group (much smaller but very important in type) that must be considered which includes the woman who is not established and has no private practice to give her her living expenses. She must depend on a salaried job for maintenance while she is serving her country in time of war. Why should such a woman if she is professionally capable be debarred from taking an important job with proper rank and privilege? Indeed, it may be more appropriate that this unattached able woman should serve than some man who may have to relinquish his private practice and has a wife and children to care for. One hears of these public health positions for women physicians, but it is quite shocking to find how relatively few important public health jobs with proper salaries are held by women.

Again, it is argued that it would not be suitable for women physicians to go forward with the troops into action. This objection could seemingly be met by the common sense and sagacity of the officers assigning such positions. Why send a woman physician out with the troops when she might give invaluable help in a base hospital? I have in mind a number of superbly trained women in such various fields of medicine as contagion, tuberculosis, etc. Would not the American mother prefer one of these experienced skilled women in charge of her son battling for his life in some base hospital to having him in charge of some young recent male graduate with scant clinical training?

And how about our women surgeons, for we are having an increasing number of these? If they are as good as their brother surgeons and as ambitious, will they not want to go forward into action where they will see traumatic surgery and war injuries at first hand? The answer is, that that is just what they are doing. They are serving in England in British uniforms, receiving equal salary, rank, and privilege with the men

physicians of the British Emergency Medical Service of the British Government. And it is a matter of further great interest that they are already filling teaching positions in medical schools and hospitals in London.

Times have changed. We are living in a new era where vital accomplishment, not sex, is the measuring rod. The American man and woman enjoy the greatest personal freedom in the world, and it is our fervent hope that democracy will always prevail in our midst. The woman physician has come through long years of hardship, privation, and self-sacrifice. She must evolve into her final best self where she has a right to make a decision as to how she will expend her energies in the service of her beloved country. Why should she be told that she must do one type of work when she knows she can do another type better? This last shackle of injustice should be removed. Today we are dealing with a new type of war, and woman's job is irretrievably an integral part of it. Let her at least have the advantage of being a free woman before she takes up the burdens that war will bring.

I am therefore appealing to you, the men physicians of New York State who have so magnificently stood by your sister physicians, to write to

Major General James C. Magee,
The Surgeon General, United States Army,
Washington, D. C.

and request him to consider favorably the appointment of women to the Medical Reserve Corps of the Army, and to write to

Admiral Ross McIntire,
The Surgeon General, United States Navy,
Washington, D. C.

and request him to have the restriction removed and women physicians declared eligible to the Medical Reserve Corps of the Navy.

And in making such possible decision please ask them to consider the woman physician of 1942 in relation to World War No. II and not judge her by the standards of privilege which prevailed in 1917.

ENROLLMENT FORM FOR PROCUREMENT AND
ASSIGNMENT SERVICE FOR PHYSICIANS

Dr. Sam F. Seeley, Executive Officer
Procurement and Assignment Service
New Social Security Building
4th and C Streets, S.W.
Washington, D. C.

Dear Doctor Seeley:

Please enroll my name as a physician ready to give service in the Army or Navy of the United States when needed in the current emergency. I will apply to the Corps Area commander in my area when notified by your office of the desirability of such application.

Signed.....

1. Give your name in full, including your full middle name:.....
.....
2. The date of your birth:.....
3. The place of your birth:.....
4. Are you married or single?.....
5. Have you any children? If so, how many?.....
6. Do you believe yourself to be physically fit and able to meet the physical standards for the Army and Navy Medical Corps?.....
7. Have you filled out previously the questionnaire sent to all physicians by the American Medical Association?.....
8. When and where were you graduated in medicine?.....
.....
9. In what state are you licensed to practice?.....
10. Do you now hold any position which might be considered essential to the maintenance of the civilian medical needs of your community? If so, state these appointments:.....
.....
.....
11. Have you previously applied for entry into the Army or Navy Medical Service? If so, state when, where and with what result (if rejected, state why).....
.....
.....

Signature.....

Date..... Address.....
.....

ENROLLMENT FOR SERVICE IN THE ARMY AND NAVY

[Reprinted from the J.A.M.A. January 10, 1942]

Last week The Journal published an urgent request to all physicians of the United States to fill out the questionnaire published in that issue and mail it at once to Dr. Sam F. Seeley, Executive Officer of the Procurement and Assignment Service, Washington, D. C., indicating their availability to serve the nation in the present emergency. The response to this call to the medical profession to date has been highly gratifying. The following statement to that effect, with additional instructions, has been received from the Directing Board of the Procurement and Assignment Service:

The response of the physicians of the country to the Procurement and Assignment Service request for enrollment of those now ready for immediate service in the army or the navy is highly gratifying. All names are being processed, and those who meet the present demands of the Surgeon Generals will receive application forms and authority to appear for physical examination at an early date. All who are now ready for immediate duty should forward applications to the Procurement and Assignment Service at once. It is not the intention of the Procurement and Assignment Service to register every physician, dentist, and veterinarian at the present time. *Only those available for immediate assignments should register at this time.* The physical requirements of all military, governmental, industrial, and civil agencies will be published in national and state journals immediately. On the basis of this information every physician, dentist, and veterinarian will be able to make a self appraisal of his physical qualifications. Within a few weeks the Procurement and Assignment Service will mail to all individuals a form on which they will be asked to state their preferences for assignment to all agencies of national defense which require medical, dental and veterinary personnel and for service in communities in public health and other civil categories. In this way every physician, dentist, and veterinarian of the country will be able to lend maximum support to the national emergency. In order to meet the expanding needs of the military services, every physician immediately available for duty should mail his application blank to the Procurement and Assignment Service at once. All others will be given an opportunity to volunteer in the near future.

Frank H. Lahey, M.D.,
Chairman.
James E. Paullin, M.D.
Harvey B. Stone, M.D.
Harold S. Diehl, M.D.

C. Willard Camalier,
D.D.S.
Sam F. Seeley, Major,
M.C., U. S. Army,
Executive Officer.

PRESENT STATUS OF THERAPEUTIC REGIONAL ANALGESIA

E. A. ROVENSTINE, M.D., and H. M. WERTHEIM, M.D., F.A.C.S., New York City

THE control of pain is an important prerogative of the physician. This obligation has been recognized by the medical profession and demanded by the laity. Surgical anesthesia, which had its origin during the middle of the nineteenth century, was an outgrowth of this idea. It was developed to exempt the bodily pain associated with surgical procedures. Regional analgesia was employed for similar purposes and saw its beginning during the latter part of the last century. The conquest of intractable pain, especially that resulting from chronically diseased tissues, is a much broader field than surgical anesthesia. It is of paramount importance to the patient, since the prevailing practices toward efforts to control nonsurgical pain depends largely upon the use of narcotics that depress metabolic function and eventually lead to addiction.

The employment of regional analgesia has kept pace with refinements in pain therapy. Unfortunately, its advantages have been appreciated by a limited group. The lack of application and enthusiasm is readily explained. First, it is due to the failure of all but a few to master the various technic of regional blocks and, second, it is because of promiscuous attempts at nerve block, often performed without accurate segmental localization. Moreover, with few exceptions, therapeutic nerve block has been given the task of accomplishing results when other methods for the relief of pain have failed or were expected to result in drug addiction. Under these circumstances—that is, a scarcity of those trained to practice therapeutic nerve blocking and a group of patients presenting the most difficult problems for pain relief—it is to be expected that the end results will still leave much to be desired.

It is readily admitted that there is no logical plea for relieving pain by nerve block if other therapeutic efforts are sufficient, save that of continuous use of hypnotics or opiates. Patients are subjects for therapeutic nerve blocks only after judicious medical treatment has failed to relieve pain or when surgical transection of sensory pathways is considered a grave hazard. It should be realized, how-

ever, that in the group for whom surgery is contemplated there may be a considerable number who should be given the advantage of less radical intervention by therapeutic nerve block, since operation may always be performed.

There is a logical plea for a more generous regard of the usefulness of nerve blocking. Failures with a few or even many patients who have not been helped by other treatment is no reason to condemn a procedure that is frequently successful. Likewise, a nerve block that obviates a dangerous neurosurgical operation for even a small percentage of patients is valuable. Such statements are made advisedly, since in competent hands nerve blocking does not add to the patient's discomfort, except temporarily in some cases during the manipulation, and is infrequently attended with untoward reactions of consequence.

There have been a number of therapeutic nerve blocks recently brought nearer perfection and many more have been newly introduced. It would be presumptuous to say that all these therapeutic adjustments should assume a definite place in the treatment of pain, for experience with them has neither been extensive nor has it stood the test of uniformly successful results. Sufficient data have been accumulated, however, to insist that therapeutic nerve blocking merits further trial and more widespread application. It is not the purpose of this discussion to recommend or describe the many nerve blocks employed by those particularly interested in this practice. Neither would it be of significant value to enumerate those that have been enthusiastically reported in the medical literature. It should suffice to point out certain nerve blocks that have been found from experience to have definite value. A detailed anatomic or technical discussion of these manipulations will not be attempted.

Nerve Blocks of the Head and Neck

Regional analgesic blocks for the relief of pain of the head and neck are among those most frequently employed. The efficacy of blocks for the relief of trigeminal neuralgia is unquestioned. If the diagnosis is without error and if the analgesic solutions are properly placed, pain relief will always be obtained. The duration of analgesia is dependent upon

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941

From the Division of Surgery, Department of Anesthesia, New York University College of Medicine, and the Third Surgical Division, Bellevue Hospital.

several factors. It is known that failures decrease and that the duration of effective results increases with the experience of the operator. Before neurolytic solutions are injected at the designated site an accurate diagnosis should be made. This is not always simple, since many pathologic conditions produce pain in the face. In trigeminal neuralgia the mandibular division is most often the pathway of pain; then, the maxillary; last, the ophthalmic. Nerve block should be performed for the nerve supply of the painful distribution only. When all the divisions are involved the gasserian ganglion should be injected.

Neuralgia of the greater occipital nerve is generally associated with arteriosclerosis. It may be explained on that basis by the direct pressure from a tortuous hardened vertebral artery on the first cervical nerve, or the etiology may be unknown. The pain is continuous and of a burning character, localized to the distribution of the posterior primary division of the second cervical nerve. Relief is readily obtained by blocking this nerve as it winds around the lateral mass of the second cervical vertebra. Procaine anesthesia is of short duration, but an oil-anesthetic or an alcohol block will be effective for months. The pain may return after a time, as it will when any peripheral sensory nerve is injected, since regeneration is inevitable.

The superior laryngeal branch of the vagus is the sensory nerve supply to the larynx. A small amount of analgesic solution properly deposited to block this nerve may be used for the control of intractable pain from carcinoma or tuberculosis of the larynx. Such a nerve block is desirable, for in these conditions, when pain is abolished, patients can ingest food and this may improve the general condition. In those cases where the pain is not localized but has spread to the pharynx, fauces, and soft palate—structures not supplied by the superior laryngeal nerve—the relief obtained may often be gratifying. The reported failures with the manipulation must be explained by a failure to bring the analgesic fluid in intimate contact with the nerve by placing the needle point in the exact plane of tissue in which the nerve lies.

Cervical plexus neuralgia is a clinical entity often confused with brachial plexus neuralgia. True cervical plexus neuralgia is characterized by superficial pain limited to a capelike distribution from the chin-ear line to the anterior thorax as far as the level of the second rib, the upper third of the arm, and the back

to the level of the scapula. The disturbance is usually limited to a single segment and is frequently caused by osteoarthritis. Blocking of the segment involved will relieve the pain. Alcohol may be used without fear of secondary motor paralysis if a single nerve is blocked.

Brachial plexus neuralgia may result from spasm of the scalenus anticus, osteoarthritis of the cervical or upper thoracic vertebra, and many other conditions. These conditions must be carefully differentiated if nerve block is to be successful. If individual nerve segments are involved and the pain can be localized, procaine-alcohol nerve block may be used. It is strongly advised that alcohol injections be limited to a single nerve at any one time to avoid serious disturbance with motor function. Muscle groups have several segmental nerve supplies and, if motor disturbance results from anesthetic section of one segment, it will not be complete. Subsequent injections may be limited then to preserve motor function.

Shoulder pain is common. The so-called rheumatic conditions, such as periartthritis or the more common subdeltoid bursitis, account for the majority of diagnoses. In the latter condition particularly, pain relief may often be obtained by blocking the suprascapular nerve at the lesser scapular notch with procaine or oil-procaine solutions.¹ The sensory components of this nerve form a vital pathway for pain fibers from the scapulohumeral and acromioclavicular joints and periarterial structures about the shoulder joint. Since the articular and periarticular branches leave the nerve in the infraspinatus and supraspinatus fossae it is not possible to interrupt them by brachial plexus block. The block is more useful in acute than in chronic conditions.

Paravertebral Nerve Blocks

Thoracic paravertebral nerve blocking, segmental and sympathetic, has numerous specific indications. The segmental nerves are blocked for intercostal neuralgia with good results. The pain associated with fracture of the ribs may be relieved by similar injections which include the nerve supply to the fractured bones.² This procedure is recommended as prophylaxis against respiratory complications as well as for pain relief. After analgesia is established, the patient will cooperate in clearing the secretions from the lower part of his respiratory tract by coughing and, thereby, minimize the incidence of atelectasis and subsequent pneumonia. The paravertebral approach is superior and more easily accom-

plished than attempts to interrupt each intercostal nerve.

Paravertebral nerve block has been used to alleviate pain associated with herpes zoster, but the results are not gratifying since the pathology is proximal to the site of injection and, therefore, the pathway is not interrupted. However, patients whose pain is initiated or exaggerated by skin stimulation will be greatly relieved, and these should have routinely an attempt to secure relief with procaine. If relief of pain is complete, then alcohol may be injected.

Another frequent use for thoracic paravertebral nerve block is for the control of pain following operations in the upper part of the abdomen or on the thorax. Such nerve blocks have a definite field of usefulness in surgical anesthesia and, when employed for this purpose, may be performed to include the control of postoperative pain.

Blocking the thoracic sympathetic ganglia has wide application in the therapy of pain. Interruption of sympathetic pathways at the stellate ganglion is used for the cure of hyperhidrosis of the upper extremity. The block is also indicated in conjunction with thoracic sympathetic blocks for the relief of causalgia, sympatheticalgia of the face, and similar painful conditions in which the autonomic nervous system may be involved. The posterior approach, contacting the body, then neck, of the first rib, has greatly minimized technical complications with stellate ganglion block and simplified the procedure.

The relief of pain arising from the various forms of cardio-aortic disease by alcohol injection of the upper thoracic sympathetic ganglia is established by the large number of successful cases reported. White has stated recently that experimental and clinical evidence point definitely to the superiority of alcohol injection over cervical sympathectomy, since the latter procedures fail to interrupt the direct thoracic cardiac nerves.³ Our results with nerve block substantiate his opinion. It is generally conceded that alcohol injections should not be the early or exclusive treatment for cardiac pain. It should be applied only when medical treatment has failed to bring adequate relief of pain. The age of the patient, his physical condition, or the severity or type of his heart disease is of little consideration in selecting patients for therapeutic nerve block. Severe angina and the failure of other nonsurgical treatments indicate alcohol injection. Individual preference, determined by experience, governs the extent

of the block, but all agree that the four upper ganglia should be included. The practice of completing the injections of different ganglia at intervals of twenty-four hours has been utilized here with success. The treatment should always be directed toward the side with severest pain, and bilateral injections should never be attempted without an interval of a week or more. If, following a successful block, attacks of paroxysmal pain recur, the block may be repeated. One such case here is that of an aged woman who has been injected on three occasions at almost exactly six-month intervals. The last two treatments were at her own request and gave complete satisfaction. Two other patients had the block performed as an emergency measure to relieve agonizing pain that had been continuous for seventy-two and sixty hours, respectively, without effective relief from what was considered dangerous amounts of morphine.

Excruciating pain may result from an aneurysm of the arch or descending aorta when the structures in the thorax are compressed or the bones eroded. Paravertebral injections of procaine followed by alcohol offer means for controlling or alleviating this distressing pain in a majority of patients. It is to be preferred to surgical intervention, since the large majority are poor surgical risks. It is advised that the ganglia corresponding to the area of segmental skin hyperesthesia, as well as the upper thoracic, be injected. The extent of each block will need to be determined by the condition of the patient and the effects from the preliminary procaine injections.

Paravertebral lumbar nerve block has wide application in the therapy of pain. Interruption of lumbar sympathetic pathways are indicated for painful conditions in the lower extremities which are similar to those already enumerated for the thoracic sympathetics. Of particular interest is the recently introduced use of lumbar sympathetic ganglia injections for the relief of pain accompanying phlebitis of the lower extremities. This manipulation has been uniformly successful not only in relieving pain but in arresting the whole process and bringing about a return to normal. It is the rule following such a nerve block to have immediate pain relief and a rapid decrease in the swelling and temperature. If procaine is used alone, the block will have to be repeated one or more times. The use of alcohol more frequently gives a satisfactory therapeutic result after a single injection. The application of lumbar sympathetic block has regularly been followed by such ef-

fective relief of phlebitis that its definite indication whenever the condition develops cannot be overemphasized. The early acute cases invariably respond well, and for those of longer duration substantial benefit or complete relief is the rule.

Lumbar and sacral segmental nerves may be judiciously blocked for many painful conditions. Meralgia paraesthetica, caused by a disturbance of the external cutaneous nerve of the thigh, may be relieved by injecting the second and third lumbar nerves. Neurodocitis involving individual lumbar nerve segments may be completely relieved by blocking the intervertebral segment close to the exit of the nerve at the intervertebral foramen.

"Sciatica" has been attacked by various nerve-blocking procedures, and satisfactory results have been reported following many of the methods employed. The nerve involvement established by accurate diagnosis may be improved, and frequently entirely relieved, by accurately placed analgesic solutions. From the experience here, the method of choice is a combination procaine injection into the body of the piriformis muscle and a paravertebral injection of procaine or an oil-anesthetic solution. Alcohol is not advised. It is usually necessary to repeat the nerve block to secure adequate relief. The piriformis is injected since it has a close relationship to the sciatic nerve, and there is the strong possibility that spasm of this muscle frequently prolongs the symptom complex.

Coccygodynia, often idiopathic in origin, has its pathways through the posterior primary divisions of the third, fourth, and fifth sacral nerves. These nerves unite to form the coccygeal nerve, which may be injected to relieve pain. This injection is also of some value in the treatment of pruritis ani.

Nerve Blocks for Carcinoma Pain

A large group of patients who may be frequently benefited by regional analgesia is that with inoperable carcinoma. These individuals rarely escape severe pain during therapy or the progression of the disease. The pain is most difficult to localize and to treat with nerve blocking. It is of utmost importance that some type of physiologic nerve section be used, for without recourse to these procedures there is often little to be done other than to use morphine in progressively increasing and ineffectual doses. If the painful area and its ramifications are carefully determined, the nerve supply may often be interrupted by

procaine and alcohol injections. Lesions about the face and neck that do not involve the deeper structures are often associated with the cervical or the trigeminal nerves and are available for blocking. Thoracic involvement is frequently relieved by paravertebral injections. Malignancies of the abdominal and pelvic viscera offer the greatest difficulties, since the pain pathways are not easily defined and are regularly extensive. No more can be advised than that the anesthetist study every case carefully from the standpoint of the position of the lesion and the cutaneous sensory nerve involvement in an attempt to select the site of injection applicable. The peripheral nerves involved may often be paralyzed, with gratifying pain relief, and epidural injections are frequently useful. It is surely true that regional nerve block should be used for these patients prior to the more drastic intrathecal alcohol or the more serious chordotomy.

Summary

A problem of magnitude in the practice of every physician is the control of pain. Many patients whose primary or sole reason for seeking medical aid is the relief of pain go without benefit from medical therapy. Not a few have added to their disorder—addiction to morphine or other drugs. Therapeutic adjustments by physical and surgical means have many failures and, not infrequently, the latter may result in added disability or may seriously endanger life. Regional anesthesia has a place in the therapy of pain. It is no panacea and is not a method of wide application. It has, however, given gratifying results in certain clinics where it has been carefully evaluated and applied for a number of patients who had experienced unsatisfactory results from other methods of pain relief. It has the advantage of relative safety and noninterference with other forms of treatment and is not often followed by serious complications when properly executed. The practice has not been accorded the consideration it merits or the careful study it deserves.

A number of painful afflictions that may be attacked by nerve blocking in conjunction with other therapy or before more radical therapy is attempted have been enumerated and briefly discussed. In our experience the percentage of patients enjoying partial or complete pain relief from such afflictions is sufficiently high to merit the recommendation that such therapeutic nerve blocks be continued.

Discussion

Dr. Paul W. Searles, *Buffalo, New York*—The method of abolishing pain by nerve block logically falls in the anesthetist's field. From my experience the internist and surgeon are glad to turn over these patients to a man who makes it his specialty to know where and how to render a nerve anesthetic. I know that abolishing pain in those patients who have usually run the gauntlet of treatment before nerve block is resorted to are extremely grateful for any relief obtained.

Several interesting cases have come to my attention during the past year. I performed a lumbar sympathetic block on a boy who had developed a painful foot several weeks after sustaining a fractured ankle. He was unable to walk on his foot. After the injection he had complete relief of pain and was able to walk on his foot an hour later.

In another patient a brachial plexus block was performed because of severe pain in the right supraclavicular region and shoulder. Pain was also present on extreme twisting and bending of head to the right, resembling a torticollis. The condition had been treated by x-ray, heat, and head traction for one month before I saw him. On completion of the brachial plexus block, the patient was relieved of pain and was able to straighten his neck without difficulty. The only complication was a pneumothorax on the right side. I doubt that this complication was due to the needle being inserted in the apex of the pleura. An x-ray showed an old inflammatory process there, and numerous evidences of scar tissue that may have been the original cause

of the pain. Anesthesia may have permitted him to break these adhesions and also tear a small hole in his pleura. The pneumothorax cleared up and patient has had no recurrence.

I have performed several stellate ganglion blocks to determine the feasibility of doing a sympathectomy for Raynaud's disease. One interesting finding was that a brachial plexus block gave us the same changes in skin temperatures as was obtained in the stellate ganglion block.

Obstinate cases of pain in the back have been a great source of interest to me. I have found that these cases usually involve more than one nerve and frequently do not clear up on paravertebral injections. Frequently, these patients exhibit a faulty posture. Good results are obtained by correction of posture. The results of these experiments have been gratifying.

I have done two lumbar sympathetic blocks for phlebitis. In both cases the phlebitis cleared up. In this, I am not certain that the other forms of therapy used were not also factors in the cure of the phlebitis.

Dr. Rovenstine (*Concluding Remarks*)—I want to thank Dr. Searle for his discussion and the recital of some of his personal experiences with therapeutic nerve blocking. The mention of nerve blocks for diagnosis impels me to say that in diagnosis and prognosis nerve blocking has attained a degree of precision that commands its use in numerous conditions. For example, there are the carotid sinus block and the various blocks used to differentiate peripheral vascular diseases and the anesthetic blocks that are accomplished before operation for hypertension are undertaken. Many others could be cited as accurate diagnostic and prognostic procedures. The ramifications of anesthetic nerve blocking have extended to more than surgical anesthesia and therapeutic analgesia.

MISSISSIPPI VALLEY MEDICAL SOCIETY 1942 ESSAY CONTEST

The Mississippi Valley Medical Society offers annually a cash prize of \$100, a gold medal, and a certificate of award for the best unpublished essay on any subject of general medical interest (including medical economics) and of practical value to the general practitioner of medicine. Certificates of merit may also be granted to the physicians whose essays are rated second and third best. Contestants must be members of the American Medical Association who are residents of the United States.

The winner will be invited to present his contribution before the next annual meeting of the Mississippi Valley Medical Society at Quincy, Illinois, September 30 and October 1 and 2, 1942,

the Society reserving the exclusive right to first publish the essay in its official publication—the *Mississippi Valley Medical Journal* (incorporating the *Radiologic Review*).

All contributions shall not exceed 5,000 words, be typewritten in English in manuscript form, be submitted in five copies, and must be received not later than May 1, 1942. The winning essay of the 1941 contest appears in the January, 1942, issue of the *Mississippi Valley Medical Journal* (Quincy, Illinois). Further details may be secured from Harold Swanberg, M.D., secretary, Mississippi Valley Medical Society, 209-224 W.C.U. Building, Quincy, Illinois.

OPHTHALMOSCOPIC FINDINGS VERSUS SINUSITIS

ARTHUR J. BEDELL, M.D., D.Sc., LL.D., Albany, New York

THE object of this paper is to stimulate interest in a large group of patients who are either told, or believe, they have "sinus" when in reality they are suffering from something entirely different.

"Sinus" has become a household word. Any pain or discomfort referable to the head is called "sinus" by many laymen and physicians. The dangers inherent in such a lack of discrimination should be apparent to everyone.

That the sinuses may be infected is admitted, that eye diseases such as optic neuritis may result from sinusitis is conceded, and that the anatomic relationships of optic nerves and sinuses are intimate is well recognized. In 1911 Onodi demonstrated his marvelous collection of sinus dissections and showed me the various associations of optic nerves, ethmoids, and sphenoids.

It must be understood that a complete eye examination includes a careful ophthalmoscopic investigation, visual field tests, the determination of ocular tension, and central visual acuity.

The general practitioner should use the ophthalmoscope as part of his routine physical inspection. If any fundus abnormality is discovered then the patient can be referred to a competent ophthalmologist.

In the presentation of a few examples where the ophthalmoscopic findings enabled the physician to make the diagnosis, the reader is reminded that this is a clinical argument for a comprehensive study of the fundus pathology and must not be considered as an objection to needed sinus surgery.

Glaucoma

All physicians have been taught that increased ocular tension is glaucoma. They have been told also that the combination of severe pain about the eyes or head accompanied by a congested eyeball, a steamy cornea, a dilated pupil, and dimness of vision is pathognomonic of glaucoma, and yet time and time again I have seen typical glaucoma mistakenly treated for sinus or influenza simply because eye signs were not recognized in a patient with frontal pain, watery nose, fever, and gastrointestinal upset.

Some time ago a man was examined who gave a history of recurring nasal infections and repeated antrum, sphenoid, and ethmoid operations. He stated that his vision had been uncertain and steadily failing for several months, and yet at no time had his ocular tension been taken. He had vision of 20/30 in his right eye with a central scotoma. The vision in his left eye was 20/100 with a large, marked sector field defect. Each fundus showed a typical glaucomatous excavation of the optic nerve. The Schiotz tension in the right eye was 30.5; in the left eye, 49.

This case is presented because there are a few who believe that sinus infection is the cause of glaucoma and also to show specifically how an advanced glaucoma may escape detection when attention is focused exclusively on the sinus infections.

A 63-year-old woman had severe head pain and nausea. The vision of the right eye was 12/200; the Schiotz tension was 25.5. There was a large glaucomatous cup. The vision of the left eye was 2/200. The pupil was 6 mm. stationary. The cornea was steamy; the Schiotz tension was 90. Her field of vision was greatly contracted. There was marked iris atrophy in each eye. Fortunately, the condition was promptly diagnosed by her physician as glaucoma.

Another case of glaucoma was that of a 46-year-old woman. Her corrected vision was 20/40 in each eye. The Schiotz tension in the right was 22; in the left, 95. The glaucomatous excavation was absent in the right eye and only moderately developed in the left. The field of vision was slightly contracted in the right eye, and in the left it was reduced to less than 10 degrees in its greatest diameter.

Following a combined trephine operation, the tension was stabilized and her central visual acuity was maintained at 20/40.

Hundreds of cases of glaucoma could be cited, but these are enough to focus attention on the imperative need of early diagnosis.

Papilledema (Brain Tumor)

The loss of vision is tragic but is not comparable to the loss of life which results when an expanding brain lesion with the intra-ocular manifestation of increased intracranial pressure is not recognized and the patient is

compelled to endure prolonged medication, sinus operations, and other nonproductive treatments because the eyes were not examined and the signs of danger not appreciated.

A 46-year-old woman gave a long history of invalidism that started with laceration, influenza, and sinus infection. Since childhood she had had fainting spells, in 1932 she had difficulty in swallowing, and in 1935 she was on a liquid diet for a long time. The diagnosis was a neurosis. Four years before she had had a hysterectomy for a tumor that was reported nonmalignant. Subsequently, the diagnosis of an endocrine dyscrasia was made. Two years later she complained of some ocular discomfort, increasing vertigo, dizziness, fainting spells, and deep sinus pain.

A year ago she had a recurrence of the nasal disturbance with more severe headache. At that time her physician found that her Wassermann was negative. She had some difficulty in walking, which was ascribed to her neurosis. Her fainting spells increased in severity and frequency, and she was brought to me for examination.

The vision in her right eye was 20/40. The pupil was 3 mm. regular and active. The media were clear. There was complete obscuration of all disk detail, with an immense choked disk and a thick, heavy crown of blood surrounding it. There were many retinal hemorrhages. The vision in the left eye was 20/200. The pupil was 3 mm. regular and active. The media were clear. The papilledema was extreme. There was bilateral, horizontal nystagmus.

It was impossible to chart her fields for she was extremely ill and fainted even when the fundus photographs were taken. A diagnosis of brain tumor was made immediately.

An enormous, solid astrocytoma of the fourth ventricle, which extended to the aqueduct of Sylvius anteriorly and downward into the medulla, was removed. Unfortunately, she did not stand the shock and expired. The postmortem examination proved that the tumor had been completely removed.

A 25-year-old man said that he was being treated for a headache that his doctor ascribed to sinus and influenza. When I first saw him he had an immense papilledema in each eye with exudate and several disk and retinal hemorrhages. He was told that he had a brain tumor, although he had no ataxia, no Romberg and no adiadokocinesis. At operation, a hemangioblastoma that involved one-half of the left hemisphere of the cerebellum

and the anterior half of the vermis was removed.

The right disk then became flat with a faint overlying veil. The retinal vessels were of normal size and distribution and the vision was 20/20.

The vision of the left eye was 20/70. The disk was pale but clearly outlined. The retinal arteries were small, and the veins were reduced in caliber. In the macular region there was a definite, circular loss of the superficial layers of the retina with a dark pigmented outer ring; a secondary optic atrophy with macular degeneration.

The first case illustrates the necessity for a careful eye examination in all chronic cases, even when the eyes seem uninvolved. The second emphasizes the importance of an ophthalmoscopic study in every patient with a headache.

Optic Neuritis

Optic neuritis is always associated with a decrease in visual acuity and a demonstrable fundus change. Some patients have been treated for sinus when syphilis was the cause, as in the following case.

Several years after primary infection, a 42-year-old man complained of poor vision in the right eye, which on examination was found to be 20/70, Jaeger 16. The pupil was 3 mm. regular and active. The media were clear. There was marked swelling of the disk with loss of outline and several concentric folds in the contiguous retina. The left eye was negative. Investigation proved that he had a 4 plus Wassermann reaction. Under appropriate treatment the disk swelling promptly disappeared and the vision was restored to 20/20.

Hereditary Optic Atrophy (Leber's Disease)

Whenever a patient with a chronic disease comes under the case of some general physicians, and even some nose specialists, sinus is the wishful thinking field for ploughing and harrowing in the hope that something will eventuate and the sufferer improve. This is well illustrated by a group of curious cases collected under the heading of "hereditary optic atrophy," where the sudden, alarming loss of vision is an emergency that must be met in a calm manner not in a stampede-like state of mental confusion.

A 20-year-old boy who had seen many physicians in the larger communities in the East; who had been in several hospitals; and who had

had many lumbar punctures, several x-rays of his head, numerous metabolism tests, sinus explorations, and thyroid administrations finally came to me for an opinion. He had vision in the right eye of 1/200, a large central scotoma, and a contracted peripheral visual field. The pupil was 4 mm. regular and active, the media were clear, and the disk was pale but distinctly outlined. The retinal arteries and veins were of normal size and distribution. The macula was clear. The left eye was the same in detail. A careful analysis of the fundus appearance and the clinical findings was enough to establish this as an example of hereditary optic atrophy.

Some authors state that in Leber's disease they have found changes in the sellar region and sphenoid. This has not been confirmed in the cases I have studied.

Retrobulbar Neuritis

Sinusitis and serious eye disease come close together in retrobulbar neuritis with its early loss of vision, little change in the fundus, a scotoma, indefinite fleeting headache, and pain in the eyes when touched or moved. The difficulties of determining the etiology are always great and in many atypical cases almost overwhelming. Too often, retrobulbar neuritis is ascribed to the nasal sinuses because epinephrine applied to the nasal mucous membrane gives immediate relief with restoration of vision, but this is only ephemeral and the symptoms recur with greater severity until, finally, the diagnosis of multiple sclerosis is established.

A 25-year-old woman complained of a sudden blur in her right eye. At the time of examination the central visual acuity was 20/200. The pupil was 4 mm. regular and active. The media were clear and the disk was distinct but faintly congested. She had a small central scotoma. In a few months the vision was restored to 20/20. At that time the left eye was unaffected.

Six years later she was seen again. In the interim she had had repeated nose treatments. The vision of the right eye was 20/40 with combined hyperopic astigmatism correction 20/20. The temporal side of the disk was distinctly pale. She had a rotatory nystagmus and neurologic symptoms, which supported the diagnosis of multiple sclerosis. When last examined, 17 years after the onset, the vision of the right eye was, with correction, 20/30 and Jaeger 6. The nystagmus was unchanged, the disk pallor was not altered, and she had the same small central scotoma.

The left eye, which before that time had been clear, showed a slight pallor of the disk, and the vision was reduced to 20/40. It was practically impossible for her to walk, and the signs of multiple sclerosis were more pronounced.

The literature is replete with histories of this kind—where the patient has been "cured" by the treatment of a coincident nasal condition. A prolonged period of observation is often necessary to determine the permanency of the "cure."

Amblyopia

The amblyopias caused by the toxins of alcohol, tobacco, lead, diabetes, and various drugs deserve attention.

A 59-year-old man complained of difficulty in seeing. He had had diabetes for two years. The right eye vision was 20/70. The disk was clearly and sharply outlined with a perceptible pallor about the macular area. The fundus vessels were of normal size and distribution. The vision of the left eye was 20/200. Otherwise, it was the same as the right. He had a bilateral central scotoma.

After three months of restricted diet and insulin the central scotomas disappeared and his vision was restored to normal. It was a case of diabetic retrobulbar neuritis which might have been incorrectly diagnosed if a complete eye examination had not been made.

A 65-year-old man complained of poor sight. The vision of his right eye was 20/200. The pupil was 3 mm.; the disk was normal. The retinal vessels were negative and the macula clear. The left eye was the same as the right.

He used tobacco excessively. For some unknown reason he was on a diet from which butter and milk had been excluded. He had a marked deviation of the septum and, by transillumination, a cloudy frontal sinus. His nose was not treated. The use of tobacco was interdicted, his diet was regulated, and his recovery was prompt.

Arteriosclerosis

Arteriosclerotic changes of the cerebral vessels may inaugurate symptoms common to a variety of lesions. Sometimes they exactly simulate sinusitis of the vacuum type, and operations are performed before making the extensive investigations necessary to disclose the true nature of the cause.

A 64-year-old woman said she had been treated for a sinusitis because of a progressive loss of vision in her right eye. When I first saw her, the right eye vision was 20/20, cor-

rected to 20/20. The pupil was 3 mm. regular and active. There were a few isolated opacities in the lens cortex. The disk was of normal color, clearly and sharply outlined. The retinal vessels showed no remarkable alterations, but there were a great many small yellowish white exudate dots, especially in the lower temporal quadrant below the macula.

The left eye vision was 20/40, corrected to 20/20. The pupil was 3 mm. regular and active. There were a few isolated lens opacities. The disk was clearly outlined with a plaque of pigment on its inferior border; the retinal vessels were of normal size and distribution. There were two small areas of retinal exudate, one along the superior temporal artery and the other near the inferior temporal branch. Her blood pressure was 120/80. There were no physical signs of sinus involvement.

Three months later the fundus of the right eye was greatly altered. The macular region was surrounded by broad, dark red hemorrhages in the external layers of the retina. There were innumerable, fine yellow dots of exudate, similar to those seen on the previous visit. Those in the lower portion were thicker. The macula was pink, and from the side toward the disk there were several radiating linear yellow exudates, a partial macular star. In the left eye there had been no change since the first examination.

Drug Poisoning

Some of you may remember that a few years ago a depilatory containing thallium made many people blind. Although the drug has been officially taken off the market, it is still a potential source of retrobulbar neuritis.

A young lady came in complaining of poor vision that had gradually failed until it was 1/200 in the right eye and 2/200 in the left. She had large central scotomas. Each fundus showed a definite swelling of the nasal half of the disk with full retinal veins.

The complete physical examination failed to disclose the cause of her trouble, and only after long questioning by her family physician did she admit that she had been using a thallium depilatory.

The reason this case is of interest is because the otolaryngologist reported:

"The mucous membrane of the left antrum was injected, and some mucopurulent discharge was coming from the region of the ethmoids on this side. If the patient did not have any eye trouble, I would not advise any operation, but in view of the impairment of vision I feel that it would be wise to open the

ethmoids, particularly on the left side, and that a radical antrum operation on that side should also be done."

His report was rendered after an excellent roentgenologic examination demonstrated that the nasal accessory sinuses were clear and that there was no evidence of sclerosis of the bony walls of the sinuses or thickening of the mucosa. It is difficult to decide definitely the etiologic factor in many cases of retrobulbar neuritis.

If this citation seems too harsh to the trained otolaryngologist, let him take comfort in the knowledge that he is not guilty. If to some, usually the ones who need instructions most and who neither attend medical meetings nor read recognized medical journals, the criticism is too pointed, they are asked to review their cases, check over the final diagnoses, and resolve that in the future some unfortunates may be helped earlier and more effectively with less operative damage and lowered mortality, for sinus surgery is not without its tragic fatalities.

Optic Neuritis (Sinus)

The last case is that of a young man who was seen because the vision was reduced to 4/200 in the right eye and 1/200 in the left. There was definite swelling and engorgement of the disks, an elevation of about 1D, and marked field defects.

His sphenoid sinuses were opened, his vision was restored, and the disks became flat. When he was last seen his vision was normal and the fields of vision showed no defects. Each disk was clear, although the temporal half was pale. This seems to be a case where recovery was complete and has remained so for several years. But even yet we cannot be certain that multiple sclerosis will not develop eventually.

Summary

Some of the more common ophthalmoscopic changes have been presented in the hope that from the free and frank discussion by the proponents of early sinus operation the value of the procedures here advised may become more universally adopted.

Glaucoma must be excluded before any nose operation is undertaken.

Papilledema, choked disk, is comparatively rare in sinus infections, so that the more common causes, including brain tumor, must be excluded before a hypothetical sinusitis is treated.

Optic neuritis or retrobulbar neuritis may

come from sinus infection, but they are more often the result of a constitutional disease that must be eliminated before nose treatment is started.

Hereditary optic atrophy, an abiotrophy, is not influenced by nose or sinus surgery.

The symptoms of multiple sclerosis and toxic amblyopia must be understood by the diagnostician and due value placed upon them before the sinuses are operated upon.

Arteriosclerosis may simulate sinusitis.

Optic neuritis can be cured by sinus surgery only when the sinuses are infected and are the activating cause of the eye disease.

Conclusion

Four groups are concerned with the sinus problem: first, the laymen, who should be told they are incompetent to make a diagnosis of sinus infection; second, the specialists who treat eye, ear, nose, or throat must refuse to become narrow in their outlook; third, alert family physicians who should welcome and appreciate instruction along the lines here recorded; and, finally, unscrupulous drug advertisers who should not be permitted to prey upon the unsuspecting public, for the use of nostrums is often responsible for serious delay in the institution of appropriate treatment.

Discussion

Dr. David F. Gillette, *Syracuse, New York*—Dr. Bedell's paper, unfortunately, will not reach the needy. They either will not or cannot make use of the opportunities these discussions offer.

This apathy should be met in a two-way educational program: (1) the awakening of these practitioners to their responsibilities to their public, and (2) the enlightenment of the layman in his essential medical matters. The success of the latter will force the former.

The former should start with the medical student and continue to the practitioner through the state and local medical societies and review courses offered by many medical schools. The latter should be conducted by the profession, beginning at the consultation and continuing through programs endorsed by our medical societies.

There are many personally important medical problems that the layman should know, concerning which he is now ignorant and confused. For example, we know that the terms "ophthalmologist," "oculist," "optician," and "optometrist" are confusing to him, for he knows each as

"doctor." The term "eye physician" substituted for "eye specialist" in the literature of the State Commission for the Blind is self-explanatory and sufficient.

In this day of ether waves we must also become air-minded, for the atmosphere is crowded with "medical shows" deluxe, offering lucrative prizes along with alluring pleas to use "medically endorsed" cigarettes for irritated throats, as well as drops, pills, powders, vapors, and salves for the quick relief of headache, head cold, sore, tired eyes, and sinus disease.

A way to help combat this and gain the public confidence is for the physician to make a correct diagnosis as early as is possible and then prescribe. It is not a sign of ignorance nor is it a sin to use the necessary aids to this end.

Those chiefly concerned with an early correct diagnosis are the patient, his physician and, in this case, his eye specialist, who should be a competent eye physician rather than a refractionist.

There are those who will continue repeatedly to sell glasses to a patient so long as he can see to pay and, occasionally, when he can do only the latter. These men are the greatest offenders, for many cases of chronic, simple, even absolute glaucoma and other grave ocular diseases are carried along until the second eye is hopelessly involved.

The two-way educational program should help to remedy and, in the future, prevent these faults.

Dr. Bedell's cases of glaucoma are uncommon only in their mistaken early diagnosis. We, too frequently, see them diagnosed not as "sinus" but as "cataracts" or "keratitis." Unfortunately, many of these are seen too late to conserve vision.

His cases of multiple sclerosis should put us on guard, for the early case is most difficult and, at times, seemingly impossible to diagnose. However, a careful history will sometimes help, for nearly every case has had an early diplopia or increasing phoria. It is possible that the occlusion test would show early marked imbalance in these latter cases.

Such a history and findings in the presence of reduced vision should be sufficient to put the consultant on the alert for a scotoma. We should use the perimeter and scotometer more often.

Dr. Bedell presented cases of drug reaction but did not mention allergy. There are cases of sinusitis, headache, and retrobulbar neuritis caused by this little understood phenomenon. Drugs, foods, and other proteins may produce these tissue reactions.

We should all be grateful to Dr. Bedell for his presentation of this stimulating review.

THE DISSEMINATION OF TUBERCLE BACILLI FROM FRESH AUTOPSY MATERIAL

RUELL A. SLOAN, M.D., Buffalo, New York*

THIS presentation is a preliminary report upon a subject that is important from a public health standpoint, especially to medical school and hospital personnel throughout the country.

During a discussion of the various methods of dissemination of the tubercle bacillus, past rumors were unearthed which led members of our department to wonder whether fresh autopsy material was not a potent source of atmospheric contamination. Mention was made of the isolation of acid-fast organisms from the surface of eyeglasses worn during an autopsy on an active case of tuberculosis. It had also been noted that the incidence of tuberculosis among medical students appeared to be proportional to their contact with autopsy material during the second year in medical school. Correlation of these rumors with the physical characteristics of the aerated lung led us to believe that the method of examination, coupled with the presence of air in the lung, might possibly be responsible for the dissemination of bacteria from fresh tuberculous material. Compression of the crepitant lung, causing expulsion of minute amounts of bacteria-laden air, might simulate a human cough in the manner of bacteria dissemination.

Another purpose of this study was to test the validity of the frequently repeated statement that fresh autopsy material, due to the adhesive properties of the surface moisture, is relatively innocuous as an air contaminant.

With these ideas in mind, equipment was designed to make possible a study of the problem. A glass-enclosed elevating shield, 22 by 26 by 13 inches, was constructed. This shield was equipped with a centrally placed glass plate, 20 by 14 inches, situated 8 inches directly above the specimen.

Procedure of Examination

Before and during the examination period, necessary precautions were taken so that all drafts from fans, open windows, and the like

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Edward J. Meyer Memorial Hospital, Buffalo.

* Dr. Ruell A. Sloan is now a member of the Department of Pathology, Children's Hospital, Boston.

were prevented. During examination the lungs were partially cut into two or three longitudinal sections, and each section was tested for crepitation. The trachea was opened, regional lymph nodes were examined, and all cavities were opened with scissors. Special mention is made of the compression of all cut surfaces and the use of scissors, because these two means of examination are too frequently overemphasized by medical students and junior pathology interns. No undue sudden movements that would predispose to splashing were allowed.

For the sake of uniformity, only the lungs from patients dying of pulmonary tuberculosis were used. After a fifteen-minute examining period of multiple section and dissection, the glass plate was inverted and washed with 10 cc. of sterile saline solution and the washings were centrifugated. Following centrifugation, the sediment was used to make four smears. After routine concentration the remaining fluid was cultured on egg albumin-glycerin mediums. Because of Corper's theory¹ that it is necessary to have 100,000 tubercle bacilli per cubic centimeter of sputum before they can be recognized with the Ziehl-Neelson staining technic and also because of the recently demonstrated superiority of the fluorescent method of Richards and Miller² for acid-fast organisms, it was decided to use the latter method, employing the routine Ziehl-Neelson technic for comparison.

In Table 1, 8 of the 10 cases tested showed a growth of tubercle bacilli in periods varying from twelve to fifty-one days. Gross examination of the glass plate showed it to appear similar to the predissection period. In only a few instances was there a sufficient number of minute, dried droplets to make the glass appear spotted.

A finding, incidental to the present study, is the marked discrepancy between the Ziehl-Neelson and fluorescent methods of staining. In the former, only 3 of the 8 cases were positive, in contrast to 100 per cent detection by the fluorescent method, on the basis of positive cultures.

Case 4 is of interest as shown in Table 2, which describes the physical characteristics of the lungs examined.

TABLE 1—DISSEMINATION OF TUBERCLE BACILLI—8-INCH DISTANCE

Case	Smears		Cultures	Remarks
	Fluorescent	Ziehl-Neelson		
1	Positive	Negative	16 days	Spot gross blood
2	Negative	Negative	Negative	Glass appeared clean
3	Negative	Negative	Negative	Glass appeared clean
4	Positive	Positive	12 days	Many dried droplets
5	Positive	Positive	51 days	Few dried droplets
6	Positive	Positive	22 days	Glass appeared clean
7	Positive	Negative	20 days	Few dried droplets
8	Positive	Negative	15 days	Glass appeared clean
9	Positive	Negative	17 days	Glass appeared clean
10	Positive	Negative	17 days	Glass appeared clean

TABLE 2—PHYSICAL CHARACTERISTICS OF LUNGS

Case	Diagnosis	Fibrosis	Edema	Crepitation (Obstructive emphysema)	Cultures
1	Pulmonary tuberculosis, III	3 plus	1 plus	1 plus	Positive—16
2	Pulmonary tuberculosis, III	3 plus	1 plus	Minimal	Negative
3	Pulmonary tuberculosis, III	3 plus	1 plus	Minimal	Negative
4	Pulmonary tuberculosis, III	Minimal	2 plus	3 plus	Positive—12
5	Pulmonary tuberculosis, III	3 plus	1 plus	Minimal	Positive—51
6	Pulmonary tuberculosis, III	2 plus	1 plus	2 plus	Positive—22
7	Pulmonary tuberculosis, III	2 plus	1 plus	2 plus	Positive—20
8	Pulmonary tuberculosis, III	1 plus	2 plus	2 plus	Positive—15
9	Pulmonary tuberculosis, III	1 plus	2 plus	1 plus	Positive—17
10	Pulmonary tuberculosis, III	1 plus	2 plus	2 plus	Positive—17

In Table 2 the comparative amounts of edema, fibrosis, and aeration of the lungs are tabulated. Case 4, previously referred to, shows fibrosis to be minimal, while aeration is marked. Compression of this lung produced numerous droplets and resulted in a glass plate that was definitely spattered. Smears and cultures were strongly positive. The Ziehl-Neelson smears showed as many as 5 to 7 organisms per oil-immersion field, comparable to a Gaffky V to VI. Growth on the cultures occurred within twelve days, a relatively short period even when grown from positive sputum. In general, the degree of dissemination appeared to be inversely pro-

portional to the amount of fibrosis or directly proportional to the amount of enclosed air.

Conclusions

First, methods of examination which make use of a compression technic contaminate the atmosphere in the vicinity of the autopsy.

Second, within the limitations of this study, fresh tuberculous lungs are decidedly dangerous and are a potent source of atmospheric contamination against which methods of proper protection should be devised.

RECTOCELE

A Constant Lesion Frequently Overlooked in Standard Repairs

JOSHUA WILLIAM DAVIES, A.B., M.D., F.A.C.S., New York City

THE passage of a child through the bony pelvis incurs a certain amount of anxiety for the obstetrician—"Will it pass?" After that uncertainty has been relieved, as evidenced by the bulging of the skin and the muscles of the pelvic outlet, the obstetrician must continue to wait for the complete delivery until the perineum has retracted over the presenting part. The mother at this time occupies his first consideration, because a hasty delivery may unnecessarily damage and perhaps incapacitate her for life.

As the head attempts to pass through the soft parts they must be enormously distended to permit delivery. The pain accompanying this process invokes a spasm of the voluntary muscles which tends to repress the final stage of labor. This spasm, however, is overcome by the gradual descent and retraction of the presenting part which, after a reasonable time, brings about fatigue in the voluntary muscles. Once they are fatigued it is merely a short while before the fascia surrounding the muscles stretches and permits retraction over the presenting part.

A reasonable delay at the pelvic outlet is desirable, for a precipitous delivery may bring about a sudden change in intracranial pressure and thereby damage the child or the mother may be lacerated abnormally. There is a limit, however, on the time that the head should be permitted to pound the pelvic floor. Experience has shown that both haste and delay are productive of lesions that weaken the musculo-fascial components of the pelvic outlet.

We are all familiar with the patient whose voluntary muscles have been fatigued by the constant pounding of the perineum and yet, instead of retracting over the head, the entire perineum bulges beyond the pubic arch because the fibrous tissue deep to the levator resists stretching. Suddenly it gives way and delivery is rapidly completed. Inspection of these cases may fail to reveal a laceration of

the skin, and the tired obstetrician is buoyed up because he has no repair to perform. It is only after the anxiety of delivering the child has passed and the mother returns for an evaluation of her physical condition that the obstetrician very readily learns that the process of labor in some women is accompanied by definite lesions. Such lesions, while slightly disfiguring, are not disabling and cause only mild inconvenience. With time, and particularly at the menopause, the slight tear under the influence of intra-abdominal pressure may deflect the force of extrusion to other structures and eventually bring about a general relaxation similar to that immediately after labor. The patient now notices that she tires easily and prefers not to stand for long periods of time. Accessory voluntary muscles, such as the legs, are used to exert pressure and afford temporary relief. In almost any group of women it is not difficult to find a relatively young woman who would otherwise be happy and aggressively occupied were she not handicapped by a minor lesion that might have been prevented. Women having such a complaint should be educated to seek relief early. The lesion, because of its very nature, becomes progressively worse, so that early reconstruction will go a long way in our effort to sponsor a happy, cooperative home.

It is my impression that the levator ani muscle, particularly the iliac portion, dilates the anus by its contraction. The pubococcygeal portion by its contraction draws the various openings of the pelvic outlet toward the pubic bone and thereby strengthens an area weakened by the perforating ducts. During the process of labor as the presenting part is forced into the pelvis, it strikes the funnel-shaped levator, and through a process of direct irritation and definite force the anus becomes dilated. The pubococcygeal portion, however, by its contraction tends to draw the dilated anus anteriorly, so that at times it may appear much easier for the head to pass through the anus than through the vaginal introitus.

In due time the pubococcygeus muscle becomes fatigued, and with the downward displacement of the coccyx the anus is drawn

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

From the Department of Anatomy, College of Physicians and Surgeons, Columbia University, and Woman's Hospital

FIG. 1. The spasm of the pubococcygeal muscle, initiated by the descent of the child, draws the anus and the coccyx forward. Pressure against the anterior rectal wall tends to stretch it and at the same time the anus may be torn from it. At this stage the anal opening is more nearly in the axis of the pelvis than is the vagina.⁴

FIG. 2. Fatigue of the pubococcygeal muscles permits the coccyx to be displaced and draw the anus posteriorly. The vagina now is in the axis of pelvis and directs the head between the two pubococcygeal muscles. The stretching of the introitus frequently tears those muscles that end or pass through the central tendon of the perineum. An extension of the tear may involve the thinned-out rectal capsule.

posteriorly, so that the line of force is now more nearly in the axis of the vagina. Not only is the posterior vaginal wall utilized in directing the head toward the vaginal introitus but the anterior wall of the rectum is likewise utilized. In many cases it is inverted into the cavity of the rectum and may be stretched considerably.

Lesions to the levator are almost always predestined to be in the same location. This predilection is caused by the head passing between the two pubococcygeal bundles under

FIG. 3. The rectum (1) bulges through a transverse tear of the rectal capsule (2). The rectovaginal mesovagina (5) are seen deep to the levator muscle. They connect the rectal capsule with the vaginal capsule and contain branches of the middle hemorrhoidal vessels which run to the posterior vaginal wall.

the guidance of the vaginal tube. The tear is usually in the central tendon of the perineum and divides the decussating muscular fibers of the levator. At the same time the transverse perineal and bulbocavernous muscles are also divided.

A casual observer could readily tell which woman needed stitches. In many patients a simple denudation and several through-and-through sutures, if done early, would suffice. Dr. Byron Goff³ has worked out a sensible technic for the repair of such cases, but to a critic's eye the vulva may still gape and the rectum may bulge, so that the general appearance is not exactly that of a woman who has never had a child. In an attempt to correct the bulging rectum, Dr. George Gray Ward¹ has described an additional lesion in the so-called "pillars" of the rectum, which lie on the abdominal surface of the levator and run from the rectum to the posterior vaginal wall. Dr. Ward utilizes this structure to support the anterior rectal wall by transplanting the anterior extremity proximal to its normal insertion.

Dr. Benjamin P. Watson² likewise utilizes this structure in his reconstruction of the pelvic outlet and, once he demonstrates it to the visiting surgeon, no operation will be complete until this firm suturable structure has been reconstructed.

FIG. 4. Traction on the rectal capsule, readily identified proximal to the crest of the rectocele, covers the defect in the anterior rectal wall. It is anchored close to the anus between the rectal attachments of the rectovaginal mesovagina.

For those who may wish a description of this flat tough tissue it may be easiest to begin higher in the abdomen where the parent layer binds the aorta in place. From the aorta the parent tissue can be traced to the kidney, where it forms the fatty capsule of this organ. In the pelvis it forms the capsule of the bladder, the vagina, and the rectum. Deep to the central tendon of the perineum this tissue is somewhat heavier than elsewhere. It connects the capsule of the rectum with the capsule of the vagina and carries branches of the middle hemorrhoidal vessels from the anterior surface of the rectum to the posterior wall of the vagina.

I prefer the descriptive term "rectovaginal mesovagina" to the indefinite terms "pillars of the rectum" or "endopelvic fascia." The rectovaginal mesovagina is of interest to those surgeons who find that after excising a segment of the posterior vaginal wall and doing a perineorrhaphy the rectum still continues to bulge into the lumen of the vagina.

The entire perineum is forced distal to the normal position between the ischial tuberosities at the end of the second stage of labor. This means that the rectum must elongate to accompany the displaced anus. The child's face, however, by compressing the rectum against the sacrum limits the stretching to an area immediately proximal to the anus. A

FIG. 5. The rectovaginal mesovagina (5) have been reapproximated with interrupted sutures. The levators (6) are located by a suture which grasps the tissue lateral to the anus. The superficial perineal muscles (7) are closed with a continuous suture.

tear in the rectovaginal mesovagina, which accompanies the tear of the central tendon of the perineum, may extend posteriorly to the stretched rectal capsule. If the capsule is involved, the extension is horizontal. It is through this transverse slit in the rectal capsule that the muscularis of the rectum bulges and becomes adherent to the posterior vaginal wall. The rectal adhesion interferes with the tonicity of the rectum and predisposes to constipation.

The reconstruction of a rectocele and a laceration of the pelvic floor should be directed to the following structures:

1. The scar in the posterior vaginal wall.
2. The lacerated capsule of the rectum.
3. Anchoring the apex of the vaginal reconstruction to the rectal capsule near the anus.

FIG. 6. A transverse suture in the posterior perineal body will draw the transverse perineal muscle (9) into the central tendon, but the retracted bulbocavernosus muscle (8) must be secured by a suture that passes lateral to the vagina in the substance of the labia minora. Failure to reattach these muscles causes the vulva to gape and removes an accessory voluntary urethral sphincter.

4. Reapproximation of the retracted rectovaginal mesovagina.

5. Reapproximation of the levators in the central perineal body.

6. Reapproximation of the deep transverse perineals, as well as the superficial perineal muscles.

7. Anchoring the retracted ends of the bulbocavernosus muscles into the posterior perineal body.

Repair

Of the various methods of approach to the damaged structures, I prefer to begin by making a triangular denudation of the skin over the central perineal body. The apex is directed toward the anus with the base at the hymen. Such a denudation removes the irregular patch of mucous membrane which lines the defect and exposes the deeper structures in the perineum. The posterior vaginal wall is then separated from the dense rectal adhesion resulting from the laceration of the capsule of the rectum and the retraction of the rectovaginal mesovagina. Following this difficult separation, the proximal area of the vagina is readily separated from the rectum. A clamp is now placed on each rectovaginal mesovagina, and traction is made anteriorly to expose their origin from the rectum. At

this point it will be noted that the rectum is devoid of a fibrous capsule and that the muscularis bulges through a transverse laceration of its capsule. Small localizing clamps are now placed on the edge of the retracted capsule, and a continuous suture is placed to reattach the retracted edge to the posterior extremity of the rectovaginal mesovagina. This procedure covers the muscularis of the rectum with a restraining capsule, offers support to the involuntary muscular fibers of the rectal wall, and thereby tends to increase the tonicity of the ampullar portion.

The scar of the posterior vaginal wall is excised and the defect is closed as far as the hymenal tabs with interrupted sutures. It is suggested that one of these sutures grasp the rectal capsule near the anus. This tends to prevent the extrusion of a tab of posterior vaginal wall which may be interpreted as a recurrent rectocele.

The preceding reconstruction has been directed to the rectal capsule and to the posterior vaginal wall. The repair of the lacerated pelvic floor is directed to the voluntary sphincters of the vagina and the layer of preperitoneal tissue, deep to the levator muscles.

The rectovaginal mesovagina is accurately closed with three or four interrupted sutures. It is this step in the usual perineorrhaphy which is frequently overlooked. The general surgeon may obtain an approximate apposition of this structure by through-and-through sutures, but the gynecologist strives to prevent recurrences by being specific in the various steps. After the reconstruction of the rectovaginal mesovagina, our attention is directed to the pubococcygeal portion of the levator muscle. These bundles need not be exposed by blunt dissection, for the placing of a suture lateral to the anus will identify the muscle as it courses to its insertion into the anus. Subsequent sutures reapproximate the pubococcygeal bundles until the introitus of the vagina is narrowed to an opening that admits two fingers. It is advisable to place all the levator sutures before tying them, because the last untied suture may be used as a retractor to identify the structure about to be reapproximated. In order to obliterate the dead space between the mesovagina and the levators and restore them to their normal anatomic position, several of the levator sutures should catch the deeper layer, particularly the suture closest to the posterior wall of the vagina.

The superficial layers of voluntary muscles may be drawn together by a continuous suture

that begins at the hymenal tab and extends anteriorly, lateral to the vagina in the substance of the labia minora, to secure the retracted bulbocavernous muscle. A similar movement secures the muscle of the opposite side and anchors the posterior extremities of the bulbocavernous muscles in the central perineal body. The transverse perineal muscles and Colles' fascia are reapproximated as the suture is continued toward the anus. Returning, intracutaneously, the suture unites the skin.

Such a technic should restore the contour of the anterior rectal wall and reconstruct a more normal perineal body. At the completion of the operation it is necessary to retract the labia minora before the hymen can be visualized. The latter requirement is particularly important in operations for urinary stress incontinence, for reattachment of the retracted bulbocavernous muscles restores the function of this muscle as an angulator of the urethra.⁵

Discussion

Dr. Edward P. McDonald, *Albany, New York*—After every delivery the pelvic floor shows evidence of injury to a greater or lesser degree. The end results of these injuries are shrinking and atrophy of the pelvic diaphragm, cystocele, rectocele, and prolapse of the uterus, all in direct proportion to the degree of injury and the structures injured.

To evaluate correctly Dr. Davies' paper, one must look at it from both the obstetric and the gynecologic points of view.

Dr. Davies has correctly pointed out that too rapid expulsion of the head *may* cause intracranial damage. It is equally true that too much pressure by the obstetrician to hold back the head in an attempt to "save the perineum" may cause similar damage to the infant.

The time has passed when the well-informed

obstetrician points with pride to the woman he has just delivered "without a tear"—i.e., a visible tear. All too often there is a submucous separation of the muscular fibers of the levator and also a tear of the rectovaginal mesovagina. For this reason, it is my opinion that almost routine episiotomy should be performed in primiparas—before these damaging lesions have occurred. If the episiotomy is a mediolateral one, it will prevent the lesions to the levator, which are almost always destined to be in the same location. A reasonable familiarity with the anatomy of the pelvic floor will enable the obstetrician to do a satisfactory repair of the episiotomy wound.

The worst type of perineum is the "bulging" one mentioned by Dr. Davies. The vulva is pushed forward with the advancing head, and it is in this type that episiotomy should be done early—under local anesthesia.

Where the obstetric care has not been of the best and where the lesions described by Dr. Davies have occurred, then his technic of repair is probably correct.

Curtis says, and rightly so, that restoration of the perineum is based upon "first, the operation of Emmett, who restored the levator ani and fascia by lateral sutures which unite and elevate the muscles and fascia; or, secondly, the operation of Hegar, who sutured the muscles and fascia in the midline." Most operators today employ a combination of these two procedures.

If one reviews the literature on the repair of rectocele, he will find a multiplicity of operative procedures, most of which are based upon the principles mentioned above. Whenever multiple procedures are advocated for the cure of any single surgical problem, one of two things usually exists. Either none of the procedures is completely satisfactory or all of the operations based on anatomic restoration give reasonably good results.

In principle, Dr. Davies, too, follows these fundamentals. Also, he brings out and stresses an important and often overlooked point—"the reapproximation of the retracted or torn rectovaginal mesovaginas"—and in doing so, he probably gives the answer to the too frequent failure of permanent cure in perineal repairs.

Dr. Davies has given in detail the steps of an excellent procedure for the repair of pelvis floor injuries, and his results should be equally good.

In his paper Dr. Davies mentions that perineal injuries have a tendency to become progressively worse, and he advocates "early reconstruction." I should like to ask him what he means by "early reconstruction."

The great Justice Holmes was once asked why he wrote his decisions at a standup desk and he

replied, "Nothing contributes to brevity like the giving of the knees."—*Wichita Medical Bulletin*

THE PROBLEM OF PRURITUS VULVAE

JAMES E. KING, M.D., Buffalo, New York

PRURITUS vulvae is an extremely unpleasant and distressing symptom. It so dominates clinically the many physical conditions that cause it that our textbooks and literature primarily consider this symptom of itching and discuss more or less incidentally the causes and pathology that will produce it. In a practical approach to the subject this is probably well. One has only to see patients showing scratch marks with excoriation and to learn of their sleepless nights, constant unrest, and suffering to realize that pruritus vulvae is a challenge to our earnest endeavors for its relief.

Necessarily, any scientific approach to the cure of pruritus vulvae means an understanding of, and ability to diagnose, the conditions that cause it. They are many. In general, the causes may be classified into four groups, and these, if borne in mind, will give the physician the basis for a rational treatment. The first group includes only one condition—an itching that is associated with no discoverable local lesion and which is designated as "idiopathic pruritus." The name itself implies that its cause is unknown. In the second group are the conditions that will produce irritation of the vulva and which may result in a full-blown dermatitis. These conditions are most frequently associated with vaginal discharges and, more rarely, to conditions of the urine such as glycosuria or by the irritation of a highly acid or infected urine. The third group consists of conditions of the vulva which are brought about by, or associated with, the withdrawal of ovarian secretion. This atrophic state of the vulva is often aggravated by factors that arise in the vagina. One of these is a simple serous or an infected discharge that may result through the loss or impairment of the vaginal protective epithelium. In the fourth group are specific conditions of the vulval area in which are found the yeast and other fungi and the more rarely encountered pediculi pubis and psoriasis. In this group may also be placed leukoplakia and kraurosis. All instances of pruritus vulvae may be found to fall into one or another of these four groups.

The idiopathic pruritus is probably due pri-

marily to nerve dysfunction. Careful search will disclose no skin lesion except that occasioned by scratching. These cases may be intractable and will cause as great suffering as other conditions due to a demonstrable etiology. The cause being unknown, there is no rational treatment, but these patients can be made comfortable by a palliative procedure to be described later.

The second group, those conditions that produce a dermatitis, is a large one and may be encountered at any time of life. Children with an irritating discharge due to a simple vaginitis or to a vulvitis from uncleanness will frequently complain of pruritus. Masturbation will occasionally supply the irritation, or at times the irritation will result in masturbation. A trichomonas vaginitis is undoubtedly the most common discharge of all to cause vulval pruritus. The recognition of this cause will suggest the successful treatment for the cure of the pruritus. In women in or past the menopause, a senile vaginitis, and a secondary infection that may result, will give rise to a disturbing pruritus. Here again, to determine the etiology leads to the cure. A vulvitis due to conditions of the urine usually presents no difficulty in diagnosis. The appearance of the vulva in glycosuria is characteristic. The vulva is a deep red, may be slightly swollen, and has a definite lack luster appearance. A urinalysis will establish the diagnosis. Treatment here will yield prompt results. Other conditions of the urine—highly acid or infected urines—will produce a vulvitis far more frequently in the very young or in those past the menopause. The treatment here suggests itself. With these four groups in mind the physician is in a position to examine the patient with pruritus with some hope of determining its cause.

First in clinical importance is the age of the patient. There are three age groups to be considered: the first group takes in the children up to the time of puberty; the second group, between puberty and the menopause; and the third group, during the menopause or after the menopause has been definitely established.

In children before puberty, the epithelium of the vagina and vulva offers relatively slight resistance to infection and irritation. In this age group a discharge from any cause may

produce pruritus, and in untreated cases a vulvitis will often develop to increase the itching and to result in secondary infection. In all of such cases an examination will show a reddened vulva, and in those instances where scratching has produced infection, a well-established vulvitis is found. On these more irritated surfaces an acid urine will cause smarting and burning that add much to the discomfort of the child. Here, inasmuch as the vulvitis dominates the picture, it is often considered as the basic etiologic factor. In my experience the basic factor is far more frequently a discharge, which at times is overlooked by the physician. It is the discharge that requires primary attention. I have found that a zinc chloride douche, to be discussed later, is more efficient and gives the best results in all vaginal discharges from whatever cause. A gonorrheal discharge in the child will occasionally cause pruritus. This may always be treated with an estrogen, either by injection or by suppository. In the children who also complain of burning on urination the urine should be rendered alkaline or neutral by appropriate remedies. Rest and applications of hot boric acid solution may also be necessary in the cases associated with marked vulvitis. In instances in childhood which show no discharge, any itching will be found to be due to diabetes or to a highly acid or infected urine. If the urine cannot be determined as the cause, pinworms or irritation from uncleanness may be suspected.

It is in the ages from puberty to the menopause that the widest variety of factors causing pruritus is found. Here one finds the idiopathic pruritus in which examination shows no discharge or condition of the vulva to explain it. The vulva will show no skin changes, but occasionally the results of scratching will be seen. Since the cause of it is unknown, one must be content to treat it as a symptom only. The treatment of these cases has always been unsatisfactory. I have found only one efficient remedy for this condition—the injection of urea and quinine solution. Its value lies in the fact that it not only gives prompt relief for several days but often several repeated injections will give relief over a period of months. When we first undertook treating these cases in this way, solutions of one-third of 1 per cent were used, and we had a constant fear that sooner or later a necrosis would result. Since this did not occur, we turned to stronger solutions and now use urea and quinine in 1 per cent solution. That no necrosis occurs is doubtless

due to the fact that the vulval bed consists of a loose connective tissue and into this the injection is made well below the skin.

Also, in this age group discharge is commonly found as an etiologic factor. The most frequent discharge encountered is that caused by the *Trichomonas vaginalis*. The itching produced, especially during the early stage, is often intense. It is rather surprising that the recognition of the cause of this discharge is so frequently overlooked. It is true that there are still problems in connection with the *T. vaginalis* that are as yet unsettled. The source of the infection, its relation to the presence of other bacteria, and the reason why it is so difficult to free the vagina of the organisms are all questions still under discussion. The diagnosis, nevertheless, is easy. In an early or untreated case the bubbly appearance of the discharge, the punctate points of redness on the cervix and vaginal walls, the more or less disagreeable but not foul odor are all that is required for a correct diagnosis. Any doubt can be cleared up or confirmation established by the warm hanging drop in which the moving organisms can be demonstrated. The importance in recognizing this infection as the cause of itching is obvious, for, if appropriate treatment is instituted, the itching is relieved promptly.

My procedure in these cases is simple and satisfactory. The douche of zinc chloride is used morning and night for three or four days, and a pledget of cotton is placed between the labia to absorb the discharge. This cotton should be frequently changed. The itching at the end of three or four days is relieved and the discharge is decreased. The patient is then given suppositories of silver picrate with instructions to use one-half of a suppository each night following the douche. The morning douche is discontinued. After the silver picrate has been used for three weeks it may be stopped, but the douche must be continued long after the patient believes herself cured. Other treatments that have been suggested have been tried, but we have been unimpressed with the results.

There are two other conditions occasionally seen in women near the menopause in this age group; one is leukoplakia and the other is an early kraurosis. These are far more commonly seen, however, after the menopause has been established. For this reason these conditions will be considered in more detail later. Because these conditions are not definitely known and because the earlier stages bear some re-

semblance to each other, such cases are frequently confused.

Diabetes is also relatively common in this age group. A diagnosis of the disease can often be established by the appearance of the vulva in patients who apply for relief of pruritis. A red lack luster labial surface always suggests a urinary examination.

Infected vaginal discharges will now and then cause pruritus. Two such cases were encountered in young unmarried women who had, strangely enough, forgotten that they had inserted at the end of menstruation a menstrual tampon. In 1 patient the tampon had remained in the vagina for nearly three months. The foul-smelling discharge and itching were easily remedied after the removal of the tampon.

Psoriasis of the vulva has rarely been seen in my experience. As a rule, however, it is easily recognized by the scales and the reddened cracked and bleeding surfaces produced by the violent scratching. Further search will probably reveal other lesions, or the patient will give a history of treatment for the disease. In these cases judicious use of x-ray or the sun lamp will often give relief. I believe, however, that such cases should be in the hands of a competent dermatologist.

In the last age group—at and after the menopause—there are a number of factors to cause pruritus. The majority of these causes result primarily from the histologic changes that take place in the genital tract by the withdrawal of ovarian secretion. The thinned epithelial surfaces of the vagina and vulva foster conditions favoring vaginal infection and to the exposure on the vulva of the nerve ends. Recognition of this fact simplifies the understanding of many cases of pruritus seen in this group and also suggests a proper treatment.

All discharges of the menopause may cause pruritus vulvae. The discharge resulting from an atrophic vaginitis is due to a slight serous exudate from the vaginal surfaces and, more especially, from the small denuded areas that so frequently are to be found upon the cervix and vaginal walls. The amount of this discharge is usually not large but is sufficient to keep the vulval surfaces moist. The thinned protective epithelium of the vulva permits irritation of the terminal nerves with itching or burning as the result. Scratching of this surface quickly causes excoriation with possible vulval infection. Furthermore, the vaginal serum affords a favorable medium for bacteria and, thus, a

simple serous vaginal discharge frequently becomes purulent. When infection does occur, the itching becomes more intense. There are two indications in these cases. The first is the use of an estrogen to promote re-establishment of a more protective epithelium, and the second is the use of an astringent douche. The zinc chloride douche meets this indication. Estrogen must be given in large dosage of 10,000 units daily until there is evidence of an improved epithelium. In cases that have been neglected until vulval dermatitis with excoriation and thickening is present, complete relief of itching can be secured by the injection of urea and quinine. Naturally, the influence of glycosuria and infected urine will cause itching in this age group much more readily than in the reproductive age group. This must be kept in mind.

There now remains for discussion leukoplakia and kraurosis. There has been much confusion in connection with these two conditions. This results from the fact that the early stages of the two conditions somewhat resemble each other. The first distinguishing feature is the fact that leukoplakia may begin at anytime during the reproductive age and kraurosis begins far more frequently at, or after, the menopause. They both develop slowly and both are, therefore, chronic diseases. Leukoplakia in its early stage appears to be an inflammatory condition that is attended by intense itching. The early stage of kraurosis causes slight itching or may be attended by no symptoms. Leukoplakia becomes a thickening and a cornification of the epithelium of the vulva, and this process may extend to the inner sides of the thighs and around the anus. Kraurosis is confined only to the vulva, and late in the disease it is characterized by a marked atrophy of all the vulval tissues. As leukoplakia develops, marked thickening occurs and whitish areas appear where a piling-up of epithelium has taken place. The intense itching and the scratching for its relief causes excoriation and fissures on the dry surfaces. As kraurosis develops, a shrinking and actual disappearance of the labia will take place leaving a shiny reddened surface that eventually becomes extremely contracted. Leukoplakia not infrequently results in vulval carcinoma. Kraurosis seldom, if ever, gives rise to malignancy. This point of difference indicates the importance of the recognition and adequate treatment of leukoplakia.

The cause of leukoplakia and kraurosis being unknown, the treatment of both are

more or less palliative. The itching of leukoplakia is intense, and the only successful palliative treatment in my experience is urea and quinine. Carcinoma in these cases develops most frequently after the menopause, and a woman with excoriations, fissures, and ulcers of the vulva is in grave danger. Such a case in my opinion should be subjected to a vulvectomy. This is a simple operation easily accomplished and should not be delayed until after actual carcinoma has developed. In addition to eliminating the danger of carcinoma, a vulvectomy will also afford relief from the itching.

Textbooks in the discussion of pruritus vulvae are inclined to emphasize ointments and washes. I have had no success with any of these. They are the product of the days when the causes of pruritus were not so well understood. X-ray as a treatment may at times give relief. In my experience I have seldom found reason to advise it. My pessimistic view as to the efficacy of x-ray has probably developed because of the fact that a certain proportion of my cases have previously been unsuccessfully treated by it.

The injection of alcohol about the vulva is effectual but so painful that an anesthetic is needed at the time of injection. Many points of injection are also required. For these reasons a solution of urea and quinine is to be preferred. It can be injected at the office and can be used freely. Three or four areas of injection on each side is usually sufficient. Some smarting occurs at times, but this usually quickly subsides. The first injection may give relief for several days, but on the re-appearance of the itching it should be repeated. Three or four injections at intervals depending upon recurrence of the itching is usually sufficient. These intervals of relief afford an opportunity to treat the cause.

The technic of the injection is simple but it must naturally be done with strict attention to antisepsis. The points selected for the injection are touched with iodine and the injection is made. I prefer the urea and quinine supplied in ampules. The insertion of the small needle is not more painful than any other hypodermic. Even in cases with excoriation and dermatitis the injection can be safely done. In only one such case was there a superficial infection at the point of injection. As has been said, in over one hundred injections no necrosis was seen. In patients

in whom the pruritus extends about the anus, small injections into this area can be made. I have never attempted to inject the pubic nerve, and I see no good reason for believing that it would be more efficient.

The zinc chloride douche that has been advised consists of hydrochloric acid 1 cc., zinc chloride 30 Gm., and distilled water 240 cc. The solution should neither be cloudy nor show a sediment. Of this solution, 8 cc. is added to 1 quart of warm water. The douche is best taken at night, since there remains in the vagina a small amount of the fluid that permits its more prolonged effect. In some instances the amount of zinc chloride may be increased. This douche will be found efficacious in practically all discharges arising within the vagina.

Summary

1. The causes of pruritus vulvae are grouped under four headings as an aid in determining the etiologic factor in a given case.

2. Pruritus is clinically classified into cases occurring in children, those occurring during the reproduction years, and those occurring at or following the menopause. This clinical classification offers help in rational treatment.

3. The palliative treatment advised is the use of urea and quinine injections about the vulva.

Discussion

Dr. J. Craig Potter, Rochester, New York— I have enjoyed listening to Dr. King's paper. Since the use of quinine and urea hydrochloride for this purpose is new to me, I have nothing to add.

I shall confine my remarks, therefore, to yeast and fungus infections of the vulva associated with pruritus. This is common, but many cases are objectively subclinical.

One must begin by asking about the condition. Modesty may prevent the patient mentioning itching. Does she or the husband have athlete's foot or other evidence of yeast infection? Most patients, thinking that extra cleanliness will help, add a soap dermatitis to the condition.

In treatment, then, stop soap. Use powder after a bath, for dryness is important. Tar, salicylic acid, and sulfur are helpful. X-ray is also valuable. Finally, the dyes, such as gentian violet, may help.

In closing, I wish to thank Dr. King for a new method of treatment which I am anxious to try.

CHRONIC HYPERTROPHIC OSTEOARTHRITIS IN THE CERVICAL SPINE WITH RADICULITIS

A Report of 40 Cases with a Review of the Literature, Together with Some Notes on Effective Methods of Treatment—Part I*

LE MOYNE COPELAND KELLY, M.D., F.A.C.P., New York City

RECENTLY, I have been impressed with the increasing incidence of hypertrophic osteoarthritis of the spine, as seen both in private and clinic practice, and have been prompted to study this condition more carefully, especially in relation to the wide variety of root symptoms which it can produce. There are many reports describing the characteristic symptoms of "peripheral neuritis," but little has been written regarding such other symptoms as headache, earache, sore throat, facial neuralgias, and pseudoangina, which at times may be part and parcel of this syndrome. Accordingly, certain interesting cases will be presented herein.

Moreover, the opinion seems to be held rather generally^{4,12,14,31} that the hypertrophic changes about spinal vertebrae, so commonly seen in the x-ray in older people, do not ordinarily cause symptoms of any kind. I want to stress the fact that many of these patients with pains in the shoulders and arms have a radiculitis from osteoarthritic changes in the cervical spine and that such changes may or may not be demonstrable in the x-ray film.

We shall limit this discussion to the symptoms that may result from pressure on the cervical spinal roots. Only the differential diagnosis and treatment will be considered here, for the subject of radiculitis in all its aspects is, indeed, a broad one. Moreover, the anatomy, pathology, and pathogenesis of this disease complex have already been so admirably treated in a paper by Gunther and Kerr¹⁸ that they need no further consideration here.

Sore Neck, Painful Shoulders, and Neuritis in the Upper Extremities

Osteoarthritis in the spine as a cause of radicular pain is not in any sense a new syndrome, for it was well known to von Bechterew⁴⁶ nearly a half century ago. In differentiating it from the condition that bears his name, he called attention to the stiffness in the spine associated with pain and degeneration of nerve roots, sometimes accompanied

by alterations in sensation or even by atrophy of certain muscles along a radicular distribution. He ascribed these changes to a pachymeningitis with subsequent compression of spinal roots. Despite this lucid description, Bassoe,⁴ nearly thirty years later, deplored "our appalling lack of objective observations." He felt that this was due in large measure to the fact that too often we ignore the possibility of this condition when making a diagnosis.

In the older English literature frequent reference was made to the occurrence of brachial neuralgia and neuritis in the rheumatic and gouty subject,³⁹ and the statement was made⁶ that—apart from injury—a gouty deforming arthritis was undoubtedly the most important factor in the causation of arm pains. Even in the nineteenth century it was recognized that involvement of the lower cervical vertebrae with osteoarthritis resulted in soreness of the neck, pains in the shoulders, and a "peripheral neuritis" of the arms, forearms, and hands.

Today, it is generally conceded that sensory symptoms are common and that almost all cases have some pain or paresthesia. Gunther and Kerr¹⁸ point out that most root pains associated with aching and soreness and aggravated by motion of the neck are due to an osteoarthritis of the cervical vertebrae. There may be some disturbance of muscle action and, at times, even a definite atrophy of one or more muscles in the arm or forearm;⁴³ when this occurs in the hand, the patient's chief complaint is usually of inability to hold small objects. One case cited in the literature⁴⁷ showed a diminution in the size of an entire extremity, whereas, in other case reports^{5,50} the process involved only certain muscles or muscle groups. In this connection, Zabriskie⁵⁶ has stressed the fact that this disease may occur in varying degree, so that in one patient it may be present without producing symptoms of any kind, while in another it may cause localized or even widespread neurologic signs.

The outstanding characteristic of this syndrome is the aggravation of all root symptoms by movement of the spine, as well as by anything that tends to increase the pressure

* Part II and Part III of this article will appear in subsequent issues.

within the spinal meninges—viz., coughing, sneezing, or straining—Dejerine's sign.¹⁰ Turner and Oppenheimer⁴² described patients who were unable to sleep in a recumbent position because of the pain that was frequently brought on; also by jarring of any sort—viz., as in walking or riding. Others¹⁹ mention raising the head from the pillow, getting out of bed, bending, lifting, or prolonged sitting as precipitating causes of episodes of pain. There seems to be no unanimity of opinion as to whether neck motion is necessarily limited in all cases. Most observers have found^{18,20} that pain in this spot is usually associated with restriction of motion, but one group,⁴² after studying this condition in a series of 50 cases over a period of four years, reported only 2 in which there was any definite limitation of motion.

Hartsock²¹ describes the symptoms as aggravated by *flexion* of the neck, which, he says, causes a "stretching of the muscles." On the other hand, most writers^{3,7,18,23} maintain that it is *hyperextension* of the spine which increases the symptoms by causing a narrowing of the canals in which these nerves lie. This would appear to be especially true in the cervical spine where the size of the canals, in relation to the nerves, is not constant but diminishes from above downward. The sixth and seventh cervical nerves, although they are the largest,³⁶ have the smallest exits from the spine. Consequently, it is not surprising that Gunther and Kerr¹⁸ found that "symptoms referable to the lower cervical spine are twice as frequent as those to the upper, since there is a greater liability to mechanical irritation in this region." In confirmation of this, Hanflig²⁰ points out that the symptoms usually vary, according to the degree of mechanical interference with the roots as they leave the spinal cord, from numbness and paresthesias, where interference is slight, to actual pain, when the disturbance is more severe.

A few cases were mentioned in the literature⁵ which showed certain phenomena of irritation—viz., spastic torticollis and flexion contractures of fingers (in which, as a rule, only one or two digits were affected). This condition is interesting and is well illustrated by one of our patients, Case 34 (see Table 1).

Case Report

Mrs. M. S., aged 55, complained of pain in the right elbow, which had radiated to the wrist and fingers, for a period of two months. Examination revealed nothing except crepitus in the left knee. However, a roentgenograph of the lower cervical spine showed thinning of the

disks between the fifth and sixth, and the sixth and seventh vertebrae, with moderately severe hypertrophic changes in the adjacent bodies. Within seven days the right hand had become numb and swollen, and after seventy-two hours the middle finger was so stiff that she could scarcely move it. At the same time she developed pain in the midscapular region. The patient was advised to have x-ray therapy but refused, saying she preferred to try physical therapy and injections of vitamin B₁. Accordingly, she received a total of 405 mg. of thiamin chloride by muscle in a period of six weeks, without benefit.

Within four weeks the third finger had become fully flexed and could not be extended without great pain. Neurologic examination at this time showed diminution in the power of abduction and adduction in the right middle finger. The extensor tendon to that finger did not respond to the same strength of faradic current which stimulated the other fingers, and the right triceps reflex was diminished. There were no sensory findings. After approximately three months of physical therapy without benefit, the patient finally consented to treatment with deep x-ray, which was given in the form of 1,300 r units (in air). This resulted in complete relief of pain and some increase in function.

According to Turner and Oppenheimer,⁴³ who studied more than 50 cases over a long period, the pain may be quite variable in location and degree. The commonest complaint, however, was pain radiating down the arm to the radial side of the forearm, associated with paresthesiae in the fingers. Most of their patients were not conscious of any pain directly in the neck but were more apt to complain of pain in one or both shoulders or between the shoulder blades. Herein rests an important consideration in making the diagnosis, for a clue to the frequency of pain in these areas lies in the often overlooked fact that the fourth cervical nerve provides the sensory fibers to the top of the shoulder, while the fifth supplies the outer aspect of the arm as far down as the elbow. The deltoid muscle itself receives fibers from both the fifth and sixth, so that it is not difficult to understand why every case presenting complaints of pain or limitation of motion in one or both shoulders warrants a thorough study of the cervical spine. Case 33 demonstrates this very well.

Case Report

Mrs. E. J., aged 35, divorced bookkeeper, complained of pain in the right side of the neck and right shoulder with weakness in the right upper extremity for a period of fifteen months and pain, numbness, and stiffness in both hands for about three months. She said she "could

38	+	+	"Sinus trouble" not relieved by fifteen treatments			None
39	+	+				Minimal changes in cervical spine
40	+	+				Moderate osteoarthritic changes in cervical spine

* All patients received physical therapy, large doses of salicylates, and 9 Brewers yeast tablets per day.

scarcely turn the pages in her ledger." Physical examination showed a stiffness of the neck muscles with crepitus in the cervical spine, left shoulder, and knees. An x-ray of the cervical spine revealed a narrowing of the disk between C 4-5 with marked lipping of the adjacent vertebrae. A complete laboratory work-up showed essentially normal findings. At subsequent visits the patient described herself as "subject to rheumatic attacks which never seemed to be the same" and stated that she had never had swelling or redness of any particular joint. She volunteered that, even before receiving physical therapy, her pains would entirely disappear at times, only to come back full force after two or three days. She remarked several times: "When my neck gets bad, my right arm gets worse, too; but most of my trouble is with my right thumb and I have to rub my arms to get life back into them."

An orthopedist who was called in consultation did not think that pressure in this patient's neck could be a likely cause of her symptoms. He favored a diagnosis of "neuritis" and recommended a high vitamin B diet. A second consultant suggested a Thomas collar to the cervical spine, which the patient had made but promptly refused to wear. No mention was made, by either one, of the possibility of benefit from deep x-ray therapy. Therapy consisted of: (1) infrared, diathermy, and salicylates (all of which gave her temporary benefit); (2) 850 mg. thiamin chloride by muscle in a period of five weeks without benefit. *Nota bene*, massage of some tender nodules at the side of the spinal column on one occasion only served to increase the pain.

A thorough study of the cervical spine is especially important, as pointed out by Hanflig,²⁰ not only in those cases which do not have enough local pathology in the shoulder to account for the symptoms but also in those patients who, although they apparently have sufficient reason for their shoulder complaints, do not respond when specific treatment is directed to the shoulder (viz., as in those cases with a calcified subdeltoid bursitis not helped by x-ray therapy).

As to the site of predilection, Elliott¹¹ describes this disease as being "selective," since it seems, as a rule, to "specialize" in the lower cervical spine. Wagenthals⁴⁷ says that although the process may be localized to other areas or, at times, be general throughout the entire vertebral column his cases showed a marked preference for the lower cervical area. Just why this is so is not definitely known. Other authors mention it,^{42,43} and Morton²³ went so far as to state that he had never seen a case in the dorsal or lumbar area. On the other hand, Parker and Adson³³ reported that only 1 out of 8 cases of vertebral osteoarthritis seen

at the Mayo Clinic in the years 1922 to 1924 was in the cervical spine. It appears, moreover, that the symptoms may be present on one or both sides of the body. In one series the author¹⁷ found them to be preponderantly bilateral, while other students of this condition^{42,47} describe the pain in their cases as generally unilateral. It has frequently been pointed out¹⁸ that this syndrome may at times result in symptoms which in many ways simulate those produced by visceral disease and that this may help to explain some of the unsatisfactory results obtained at operation.

Careful studies have been made⁴² in an attempt to correlate the incidence of this disease with age, sex, racial groupings, and the general state of health, but no direct relationship could be found. Moreover, neither the body weight, nor the length of the neck, nor the particular constitutional body type of the patient seems to play any part in the causation of this disorder. Some authors⁴⁷ feel that trauma in one form or other may be a factor—either acute injury or chronic trauma from the repeated motions of the neck over a period of years—while others⁴³ maintain that it is faulty posture that causes these repeated injuries to the intervertebral disks. Elliott¹¹ condemns the intestinal tract as the chief source of this disorder and states that "deficient elimination is a prominent—if not the sole—cause of this type of arthritis."

Case Reports

MYXOFIBROMA OF THE JEJUNUM

TIMOTHY F. X. SULLIVAN, M.D., F.A.C.S., and
WILLIAM LAWRENCE CORCORAN, M.D., F.A.C.S., New York City

THE myxofibroma is extremely rare, particularly one occurring in the jejunum. A tumor of the small intestine ceases to be only of academic interest when, by its very intrinsic displacement, the lumen of the bowel is subjected to a complete obstruction. Its practical importance must then be realized and surgical resection and anastomosis performed without delay.

Neoplasms of the small bowel are rarely found in the course of abdominal surgery. Malignant tumors of the small intestine are rare indeed, and benign tumors are found more often in the large bowel than in the small intestine. Small intestinal carcinoma, while uncommon, is found more frequently than benign tumor change.

Pathology

The structural change may be subserous or submucous, and the growth is usually directed toward the lumen, because the mucosa offers less resistance than the muscular coat of the bowel. The size is variable. They may be single or multiple, at times assuming a condition of multiple polyposis. The tumor may be sessile or pedunculated, the submucous rarely taking on the latter form. The wall of the intestine is composed of a variety of tissues—viz., the outer peritoneal coat of the endothelium, unstriated muscle, areolar tissue, and the mucous membrane, with vascular supply, from where, with the exception of the outer endothelial coat, growths may arise. The term myxofibroma implies the presence of relative proportions of muscle and fibrous tissue.

Case Report

C. McC, a white widowed woman, aged 44, had been ill at home for a three-day period when first seen on September 4, 1940. The chief complaint was as follows: onset of sudden nausea, repeated attacks of vomiting, and pain throughout the abdomen, particularly within the right upper quadrant. The abdomen was somewhat distended, and tenderness was present about both costochondral areas, presumably due to the strain of repeated vomiting. A well-established right median scar with no evidence of hernia was existent, and a palpable mass without tenderness was determined just below and lateral to this area. The past history revealed that an operation had been performed during June, 1913, at which time an acutely inflamed appendix had been removed and a co-existing right ovarian cyst was resected from that particular gland. Subsequent to this operation the patient experienced a chronic condition of constipation and gaseous accumulation, which always responded to vary-

ing degrees of catharsis and the frequent use of the enema. The probability of postoperative adhesions developing within the right lower quadrant was accepted as the causative factor. A gastrointestinal x-ray series was made during November, 1938, and no particular diagnostic findings were made from the preoperative review of those films that were available. Apart from the stubborn constipation and its associate phases of discomfort, the patient enjoyed a good measure of health and maintained her occupation as secretary to an important executive.

Procedure.—After twelve hours of observation and treatment at home, during which time a satisfactory result with enemas was obtained, vomiting was controlled by sedation, and the fundamental picture of abdominal distention, discomfort, and tenderness persisted, the patient agreed to hospitalization where the desired clinical, laboratory, x-ray, and surgical diagnostic procedures could be made and recorded.

Decision was reached whereby an attempt to relieve the now existing obstipation was made by the utilization of a molasses and milk enema. The result of this procedure was characterized by a copious fecal return along with considerable flatus. However, subsequent physical examination gave evidence of no particular progress. The surgical signs of an obstruction continued and were soon intensified when an attack of vomiting occurred, the character of the emitted material being duodenal in nature. A flat x-ray plate (Fig. 1) was now ready in order to ascertain a fluid level, and the report was as follows:

X-ray Examination Made on September 6: Abdomen.—Flat films of the abdomen show distention of the coils of small intestine with gas and fluid. Fluid levels are present in the erect position. The large intestine is collapsed. The findings indicate an obstruction of the jejunum or ileum.

Procedure.—The laboratory reports were as follows: The urinalysis was normal. The blood was counted at the time of admission and on several subsequent occasions, and the findings were as follows: The red cell count and hemoglobin were normal and at no time revealed any impairment. The original white blood count was a leukocytosis, which showed a definite increase subsequent to the bowel's response to the molasses and milk enema.

Diagnostic Summation.—The persistence of abdominal distention, and tenderness (after a copious result from the molasses and milk enema). The recurrence of nausea and vomiting, the latter becoming duodenal in character. The flat x-ray film of the abdomen disclosing the coils of small intestine to be distended with gas and fluid. The large intestine appearing as collapsed. The presence of a fluid level in the erect position. These findings indicating a roentgen diagnosis of an obstruction of the jejunum or

Workmen's Compensation

December 6, 1941

The following resolution has been received from the Industrial Board in regard to physicians' fees for attendance before the Department of Labor.

"Resolved, That under the Fee Schedule for attendance of physicians at hearings, adopted by the Industrial Board at its meeting on June 7, 1940, the Board believes that if a physician's appearance for the purpose of testifying at a hearing is required, he shall receive the \$25 or \$10 fee, according to his designation, as provided in the Schedule. If, at the same session, he is required to testify in another case, whether before the same Referee or not, he shall be entitled to receive an additional \$12.50 or \$5.00 fee, according to his designation. If the same physician is required to attend a hearing for the purpose of testifying on the same day, but at the afternoon session, he shall be entitled to receive a larger fee, even though he had appeared at a hearing in the morning session, and an additional \$12.50 or \$5.00 fee, according to his designation, for any additional case in which he may be required to testify at the same session, even though such case may come before the same Referee."

DAVID J. KALISKI, M.D., *Director*

THE MEDICAL MEN ARE NEVER SATISFIED

"The last fifty years is the inclusive period of so-called modern medicine," said Nathan B. Van Etten, past-president of the American Medical Association. "Modern medicine is the end result of the evolution of individual efforts to cure the sick, restore them to functional usefulness and to enlist community support in the prevention of disease."

Just how well this work has been done is found in statistics covering disease and mortality in all sections of this country. In New York, for instance, infant mortality was 250 per 1,000 live births in 1886—it was 34 in 1940. Diphtheria claimed 3,000 New York victims each year in 1866—in 1940 it claimed but ten. And where, in upstate New York, the tuberculosis death rate was 74.6 per 100,000 of population in 1920, it was 36.3 in 1940—about half.

Look up the records of any of the great killers of the past and you'll find that similar progress has been made. And the bulk of the credit must go to private medicine. It is private medicine that works quietly, endlessly, and patiently in the laboratories and hospitals of America. It is private medicine that encourages further development of the various public health services. It is private medicine that has set as its goal the maximum possible extension of medical service to all the people.

In this country the level of public health is the highest ever attained in the civilized world. But even that great achievement doesn't satisfy the medical men. They mean to achieve far more in the years to come. That is the way the medical mind works. It never stands still. It must always look forward.—*Ellenville Press*

CONGENITAL HEART DISEASE MANIFESTING ARRHYTHMIA IN UTERO

NATHAN M. FENICHEL, M.D., and LAWRENCE KURZROK, M.D., Brooklyn

THE following case of congenital heart disease is reported because of the unusual arrhythmia heard before birth, and the interesting electrocardiographic findings obtained soon after birth.

Case Report

Mrs. R. R., aged 30, married eight years, had her last menstrual period on March 30, 1938. Physical examination in May revealed an early pregnancy and evidence of a mitral stenosis, probably of rheumatic etiology. Her history was negative for any possible previous rheumatic infection. During the first three months of her pregnancy there occurred slight vaginal staining, which was corrected by the removal of a cervical polyp. Blood Wassermann test was negative, and urine examinations were repeatedly normal.

On December 5, 1938, one month before her delivery, a routine examination disclosed an unusual irregularity of the fetal heart sounds. They were heard distinctly, but the rhythm consisted of a series of 3 regular beats followed by a long pause almost equal in time to that of 2 regular beats. During this long interruption after each regular sequence, not even faint sounds could be heard. The arrhythmia persisted throughout the entire last month of pregnancy with slight variations. Sometimes the pause occurred after every second or fourth beat or even disappeared, so that short runs of complete regularity were occasionally manifested by the fetal heart. She had no complaints or evidence of any toxemia and felt well throughout the prenatal period.

On January 7, 1939, the patient, after a short spontaneous labor of four hours during which the cervix was lacerated, delivered a 6-pound 15-ounce boy. The infant's color at birth was good, and his breathing was established without any difficulty. On auscultation, however, his heart exhibited the same arrhythmia that was heard intrauterine—runs of 2 to 4 beats interrupted by long pauses. In the hospital the baby took nourishment well and appeared normal. An electrocardiogram was taken on the fifth day after birth by Dr. Anna E. Wagner of the Pediatric Service. This record (Fig. 1) showed right axis deviation and groups of 2 to 3 regular beats followed by intervals which were just less than the time required for two regular beats. In leads II and III especially, inverted P waves could be seen occurring just after the last of each regular sequence of QRS-T complexes. Evidently, no ventricular contractions followed these early diastolic auricular extrasystoles, since the ventricles were still in a refractory phase.

The electrocardiogram may be interpreted as demonstrating blocked auricular extrasystoles, a condition not frequently seen. From the slightly negative aberrant P waves recorded in lead I, one may hypothesize an irritable focus in the myocardium of the left auricle as the source of these blocked extrasystoles.¹

After the baby's discharge from the hospital his progress was essentially normal. At the end of a year the baby weighed 19 pounds and appeared well. His color was always good, he took nourishment satisfactorily, and dentition was not delayed. The arrhythmia continued with frequent variations throughout this year. On some occasions the heart was completely regular, at other times only occasional extrasystoles were heard, and once a typical trigeminy was observed. When the baby was two months old, a harsh grating murmur accompanied by a palpable thrill first became evident and became more pronounced as the child grew. This murmur appeared in the systolic phase only and exhibited its maximum intensity over the pulmonic area and over the sternum in the third interspace.

By the end of the year a prominent precordial bulge was apparent and the heart percussed enlarged to the left. An x-ray of the chest (Fig. 2) taken when the child was nine months showed enlargement of the heart especially to the left. The aorta appeared markedly widened and in dextraposition to the rest of the heart, and the lung fields revealed exaggerated vascular markings. The lateral plates did not elicit any more pertinent information.

While the exact nature of the congenital heart lesion cannot be diagnosed in this case, the information at hand seems to point to some arteriovenous shunt defect, such as a patent septal lesion, associated with a dextraposition of the aorta.

A review of the literature reveals other instances where an intrauterine abnormality of the fetal heart sounds was heard, aside from its common occurrence in acute fetal distress. The first such case was reported in 1854 by Massman who detected a fetal heart murmur and was then able to predict congenital heart disease in the

FIG. 1. Electrocardiogram taken on the fifth day after birth showing right axis deviation and inverted aberrant P waves in all three leads. These auricular extrasystoles occur early in ventricular diastole and are, therefore, blocked or unable to excite the ventricles.

ileum. The increasing leukocytosis. The history of postoperative gastrointestinal dysfunction, and chronic constipation. The palpation of a mass just below and lateral to a thin existing right median scar.

Such an aggregate of facts led to the performing of a laparotomy on September 6, 1940, at 8:40 p.m., the preoperative diagnosis being intestinal obstruction (due to the crystallization of peritoneal adhesions).

Operative Procedure.—The existing right paramedian scar tissue was excised, and the incision was carried down to the peritoneum, which was then opened. Several of the existing prominent formations of adhesions that seemed to be the cause of trouble were ligated and divided. These

bands appeared partially to constrict the cecum and one loop of small intestine as they established themselves between the inner aspect of the abdominal wall and caput coli; however, there was no complete compression of the intestine. The small intestine was now traced from the cecum upwards and, after completing the survey of the ileum and well along the structure of the jejunum, there was found a smooth rounded mass within the lumen of the bowel, blocking off the small intestine. This area was delivered for surface procedure, and a segment was clamped well above and below the intrinsic tumor. After the required vascular ligation of the mesentery, about 6 inches of jejunum and its contained pathology were resected by means of the actual cautery. The respective ends of the jejunum were then turned in and closed by a double row of sutures, and a lateral anastomosis was made. The repaired jejunum was returned within the abdomen and the wound was repaired in layers. The immediate postoperative condition was good.

Pathologic Report.—The pathologic report on September 6, 1940, was as follows: "Nature of specimen—intestinal resection and mass."

Gross Description: "The specimen consists of the small intestine, which measures 9.5 cm. The serosa has an area of dimpling with a bluish discoloration. The tumor mass protrudes into the lumen of the small intestine, the intrinsic displacement being complete, resulting in obstruction. The tumor mass measures 3.5 by 2 cm. possessing a definite stalk attachment, the base being ulcerated and surrounded with a shaggy ground of fine tissue. An incised section reveals a distinct capsule with a homogeneous raised surface."

Microscopic Description: "The prepared section of the tumor mass demonstrates a mucosa which is ulcerated off and largely replaced by polymorphonuclear and lymphocytic cells. Within the surrounding inflammatory zone there is a fibrous tissue change. The stroma is arranged around a central core of blood vessels and a denser fibrosis. Other sections are made up of nothing more than a loose connective tissue with spindle cells and some fibroblasts. Again, other sections reveal a cell with a stellate nucleus from which originate strands enclosing clear spaces. While some of the areas possessing fibrous and myxomatous tissue change indicate signs of activity and while there are many new blood vessels, almost resembling granulation tissue, this tumor is classified as benign."

Pathologic Diagnosis: "Myxofibroma* of the jejunum."

Postoperative Career.—The postoperative career was characterized by the desired reaction following careful intra-abdominal manipulation, with the exception of an incident of alarm, occurring on the tenth postoperative day, when a pulmonary infarct developed. This complication, with the manifestation of acute pain in the lower left thorax, cyanosis, and pulse and respiration increase, subsided after seventy-two hours' duration, and the patient improved rapidly. Efficient nursing, the Wagensteen gastric syphon, and the utilization of vitamin therapy contributed to complete recovery.

positive. He was observed for a few hours and then sent home.

He returned two days later stating that on the day following the injection of the tetanus antitoxin he had felt dizzy, was nauseated, and had vomited several times. These symptoms persisted and, therefore, he returned. He was admitted to the ward.

Physical examination revealed an acutely ill, flushed, and somewhat disoriented young man. The temperature was 103 F.; the pulse, 120 and of small volume; the respirations, 24. His speech was thick. The right eye showed a healing laceration below the eyelid. The tongue was swollen and dry and had a yellowish-white urticaria-like lesion at its tip. The uvula was moderately edematous. The lungs were clear, the heart rate was 120, and the rhythm was regular; there were no murmurs. The blood pressure could not be obtained. An examination of the abdomen showed no abnormalities.

There was a generalized adenopathy. A diffuse erythematous rash covered the face, neck, arms, and upper part of the trunk.

During the next day the mental confusion lessened and the blood pressure reading became obtainable, reaching a level of 84/54. The further clinical course was one of gradual improvement. On the fifth day of his hospital stay the temperature became normal, the blood pressure was 100/50, and the skin rash disappeared completely.

The medication given on the ward was as follows:

March 23, 1940 4 P.M. Immediately after admission 5 minims of adrenalin were given subcutaneously. Shortly afterward, 1,000 cc. of 5 per cent glucose in nor-

offspring. Hyman,² in 1930, reported 6 cases in which premature contractions of the fetal heart were heard or recorded by the phonocardiogram. In all 6 cases the arrhythmia disappeared a few days after birth, and the hearts were then found to be normal. Dipple,³ in 1934, reported a case where the fetus exhibited premature contractions and an accompanying murmur localizable to the fetal heart, so that he was able to prognosticate congenital heart disease before delivery. Roberts,⁴ in 1938, reported a case in which the fetal

heart manifested a soft whispering murmur and frequent extrasystoles. After delivery by cesarean section, the infant was cyanotic, and an examination disclosed a systolic murmur and many extrasystoles. Death occurred in forty-two hours, and on autopsy a patent interatrial septum and bicuspid aortic valve were found. The mother, interestingly enough, also suffered from congenital heart disease. Burnham,⁵ in 1939, reported a case in which the fetal heart after the seventh month of gravidity showed an irregularity consisting of a premature contraction after every 3 to 5 regular beats. Six days after an uneventful delivery the arrhythmia disappeared and the infant's heart appeared normal.

Sinus arrhythmia also is quite commonly observed in the fetal heart and apparently is of no diagnostic significance.

Summary

From a review of our case and the cases reported in the literature, it seems that a prolonged intrauterine fetal heart arrhythmia may occur not only in a heart with a congenital defect but also in an otherwise normal heart. In either instance the abnormal rhythm is usually due to extrasystoles arising from an irritable focus in the auricular myocardium. If, in addition to the irregularity, a fetal heart murmur can be detected, congenital heart disease may be prognosticated.

ELECTROCARDIOGRAPHIC CHANGES IN A CASE OF SERUM SICKNESS DUE TO TETANUS ANTITOXIN

THEODORE T. FOX, M.D., and CHARLES R. MESSELOFF, M.D., New York City

IN 1937 Clark and Kaplan¹ demonstrated structural changes in the hearts of 2 patients who had received large doses of anti-pneumococcus serum. These changes consisted of (a) proliferation of histiocytes in the mural and valvular endocardium and in the intima of the aorta, pulmonary arteries, and coronary arteries; and (b) evidence of stimulation of the interstitial mesenchymal tissue of the myocardium. In a later report Clark² offered further proof that morphologic alteration may be associated with serum disease. The amount of serum employed was apparently of no importance.

In the present communication we are reporting a case of serum sickness which showed acute and transient electrocardiographic changes. These changes assume particular significance in view of the structural alterations described.

Case Report

J. C., a white boy, aged 18, was admitted to the emergency room of the Hospital for Joint Diseases, on March 23, 1940, with a history of having sustained an injury to the right eye two days previously. Examination showed a laceration under the right eye. This was treated and a prophylactic dose of tetanus antitoxin was given. The latter was administered in divided doses over a period of two hours because the preliminary skin test was markedly

Special Article

BEWARE OF *ALWAYS* AND *NEVER*!

DONALD B. ARMSTRONG, M.D., New York City

LET us look for a moment at the relation of health education to the tuberculosis eradication movement.

The history of health education is characterized by a steady expanding utility, by a most helpful permeation of many phases of public health, and also by occasional detours along less productive or sometimes futile channels.

Basic, for instance, is the work of health education in implementing and vitalizing the medical supervision of school children; conversely, the emphasis on certain health factors has been exaggerated, such as teeth brushing in the past and probably, in the present, the alleged gross inadequacy of vitamin intake on the part of our population at large.

In the tuberculosis field, since the establishment of the National Tuberculosis Association and even earlier, health education has played an increasingly vital part in the detection, treatment, and prevention of this disease, augmenting sanitary and epidemiologic approaches to tuberculosis control. Now, with the more precise and productive use of instruments of precision in diagnosis and treatment, health education has an important task in creating a sound and sympathetic understanding on the part of the public regarding such devices and procedures as the tuberculin test, the fluoroscope, chest surgery, and the x-ray.

At present, health education seems to be tempted to concentrate upon the x-ray, which is logical enough in view of its outstanding importance when properly employed in tuberculosis detection and in the management of the patient. But in "going to town" with the x-ray, health education might, to advantage, exercise some caution. Otherwise, there is a real danger of throwing the whole tuberculosis control picture somewhat out of focus and of leading ultimately to the necessity for a costly readjustment in public understanding. Overemphasis on one factor tends always to induce an unwarranted depreciation in the value of other items in the picture.

Let us not forget that there are four equally

essential and basic approaches to the diagnosis of tuberculosis: (1) the family and clinical history of the patient; (2) his medical (and particularly chest) examination by a competent physician, with sputum examination when possible; (3) fluoroscopy; and (4) x-ray, with its reading. We should be on guard against overemphasis on items 3 and 4, and we should also not throw the first two approaches out the window. As long as we have private medical practice in this country, the private practitioner, either in his office or in the public clinic, together with salaried medical staffs, must play his part in tuberculosis control, must be carried along in the program, and must not be completely subordinated to the technician. Those responsible for medical education realize this. It is, however, apt to be unrecognized or forgotten by other workers in the public health field, mostly active on or near the periphery and making their approach through somewhat tangential channels, such as that of the professional educator, the statistician, the chemist, etc.

In the current enthusiasm for the x-ray, let us not forget that it is merely a shadow—that it needs interpretation in the light of the history and of a great variety of symptoms and signs. The doctor of medicine must be kept a part of the team. The program cannot be mechanical or technical altogether.

Yet, with disconcerting frequency at the present time, we hear speakers, often without medical training, address audiences composed of more or less uninformed laymen and willing but uncritical physicians, announcing that the whole job is now almost altogether one that depends on mass x-raying of the population. Mass x-raying of the population has its place in case finding and is guardedly advocated by progressive health departments. It may be appropriate for younger groups (with or without the tuberculin test) or for older groups as well. With a well-organized follow-up it may be in many places, at least in part, desirable and practicable, but it is by no means the whole job. It can be much less productive than the direct pursuit of contacts; the examination of selected age, sex,

		mal saline were given intravenously very slowly, over a period of five hours.

Serial electrocardiograms were taken during this time. The first tracing (Fig. 1A), taken immediately upon admission (forty-eight hours following the injection of tetanus antitoxin), showed no evidence of myocardial damage. However, when compared with the tracing taken during the period of recovery, this initial electrocardiogram must be regarded as abnormal for this individual. The electrocardiograms taken on the following day (Fig. 1B) showed a definite lowering of the QRS complex in the standard leads and a slight elevation of the ST segments in leads II and III. The ST changes were not present in the tracing taken on the following day (Fig. 1C). The tracing taken on March 29, April 1, and April 2 showed a gradual increase in the voltage of the ventricular complex in the standard leads (Fig. 1D).

Comment

It is reasonable to postulate that the electrocardiographic abnormalities described above are attributable to myocardial changes of the nature noted by Clark and Kaplan. The two other possible causative factors—the administration of epinephrine and the presence of shock—can be readily eliminated. Epinephrine when given in large doses may give rise to transient changes in the electrocardiogram.³ However, our patient received only a small dose on admission, and in spite of the readministration of the drug on a subsequent occasion, as well as the administration of daily doses of ephedrine sulfate, the electrocardiogram returned to normal. Furthermore, the patient's sensitivity to adrenalin was tested during the convalescent period. A control tracing was taken and he was given 0.7 cc. of adrenalin subcutaneously. Twenty minutes later another electrocardiogram was taken, and the only change that was noted was an increase of the heart rate from 82 to 100.

The importance of the shock factor in the present case can also be readily eliminated, since the maximum electrocardiographic changes occurred during the period when the patient had already recovered from the shock.

Summary

A case of serum sickness is presented with abnormal electrocardiographic findings. It is believed that the structural changes demonstrated in the hearts of serum sickness cases may be responsible for these changes. More frequent electrocardiographic studies in individuals with serum sickness are needed to establish the validity of our assumption.

TREATMENT OF COMMON DISEASES

A course on the treatment of common diseases, arranged by Dr. Clayton W. Greene, professor of medicine, Buffalo University School of Medicine, for the Fulton County Medical Society, will be given on Friday evenings at 9:00 P.M., alternately at Hotel Johnstown, Johnstown, New York, and Eccentric Club, Gloversville, New York. The program follows:

February 6, "Results of Modern Methods in the Treatment of Anemia," by Dr. Francis D. Leopold, assistant professor of medicine and therapeutics, Buffalo University School of Medicine.

February 13, "The Management of Arthritis, Acute and Chronic," by Dr. L. Maxwell Lockie, professor of therapeutics, Buffalo University School of Medicine.

February 20, "Practical Application of Hor-

monal Therapy," by Dr. Ivan Hekimian, assistant professor of medicine, Buffalo University School of Medicine.

February 27, "The Treatment of Common Skin Lesions," by Dr. Earl D. Osborne, professor of dermatology and syphilology, Buffalo University School of Medicine.

March 6, "The Use of Sulfanilamide and Drugs of That Group," by Dr. Clayton W. Greene.

March 13, "What Do We Know About Vitamins," by Dr. David K. Miller, professor of medicine, Buffalo University School of Medicine.

The lecture on "The Use of Sulfanilamide and Drugs of That Group" is a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of New York.

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

DEPARTMENTS OF MEDICINE AND PATHOLOGY, NEW YORK POST-GRADUATE
MEDICAL SCHOOL AND HOSPITAL, COLUMBIA UNIVERSITY

Date: November 18, 1941

Presiding: Dr. Irving S. Wright

History

DR. MAURICE BRUGER: A 61-year-old white woman was admitted to the hospital complaining of severe precordial pain which had been present for eight hours. At times this pain was located in the epigastrium. On examination, three hours after the onset of pain, her physician noted that her extremities were cold and clammy. Her pulse at that time was slow and of poor quality. The blood pressure could not be determined. She was given a hypodermic injection of morphine ($\frac{1}{2}$ grain) which relieved the pain but resulted in frequent bouts of vomiting. On admission to the wards, she complained of nausea and occasional twinges of pain in the epigastrium.

No previous history of hypertension, precordial pain, dyspnea, orthopnea, or ankle edema could be obtained. An intolerance to fatty foods had been present for five years. One brother died of "heart trouble" at 35 years of age.

On admission to the hospital her temperature was 100 F. (37.8 C.); pulse, 90 per minute; and respiration, 20 per minute. The blood pressure was now 126/86 mm. of Hg. Physical examination revealed an obese, plethoric woman in no distress other than occasional episodes of retching. There were many small nonpulsating telangiectases over the face and neck. The pupils were irregular and reacted to accommodation but not to light. Examination of the nose, mouth, neck, breasts, and chest yielded no significant findings. The heart was not enlarged to percussion; the heart sounds were of good quality. The first sound over the apex was split, and the second aortic sound equaled the second pulmonic in intensity. No murmurs were heard. The abdomen was soft, no masses were felt, and tenderness could not be elicited. There was pulsation of the dorsalis pedis and anterior tibial arteries on both sides. The biceps, triceps, and radial reflexes were present and equal on both sides. Patellar

reflexes were barely obtainable. The abdominal and achilles reflexes were absent bilaterally. Position sense was intact. Vibratory sense was absent over the knees and ankles but was present in the upper extremities.

On the morning following admission she felt perfectly well. Five minutes later, she was seized with a severe pain over the precordium which was followed by a generalized convulsion that lasted fifteen seconds. During this convulsive seizure, the heart stopped beating but respiration continued for several minutes. Death occurred before any medication could be given.

Laboratory Data. — Urinalysis: specific gravity 1.020, faint trace of protein, no sugar, no acetone, an occasional red blood cell, 10 to 12 white blood cells per high-power field, 1 to 3 finely granular and occasional hyaline casts per low-power field. An electrocardiogram taken shortly after admission was within normal limits. Blood urea nitrogen was 35.0 mg. per hundred cubic centimeters, and sugar was 100 mg. per hundred cubic centimeters. The sedimentation rate (Westergren) was 20 mm. per hour; the blood Wassermann was 4 plus; while the Kahn precipitation test was 3 plus.

Discussion

DR. ROBERT McGRATH: It seems to me there are four conditions to be considered as the possible cause of death in this patient. These are: (1) dissecting aneurysm of the aorta, (2) coronary thrombosis, (3) pulmonary embolism, and (4) coronary embolism. The last two are rather improbable. I mention coronary embolism only because of a recent report¹ of 3 cases originating from a mural thrombus attached to an atherosclerotic plaque. These cases also had an associated syphilitic aortitis. This is a rare complication, and I think it can be excluded in this case because of its rarity and the lack of clinical evidence. Pulmonary embolism can be eliminated for several reasons: factors that produce this condition, such as operative procedures, and venous thrombosis were not

or occupational groups; or other more pointed and economical approaches.

Those who are innocent of the intricacies of clinical medicine and who consequently seem to be tempted to speak with universal authority as experts in all medical specialties can readily overemphasize this factor before an indiscriminating audience. Such a "contribution" to misinformation is not dissimilar to many "science-editor" or doctor-of-philosophy interpretations of medicine in the lay press and current periodical field. There we regularly see pseudoscientific writers "sounding off" in a premature fashion regarding alleged startling advances having to do with poliomyelitis research, virus vaccine therapy, pneumococcus immunization, etc. All of this produces a costly imbalance in the sociomedical structure designed for ultimate control of preventable disease.

Such misinterpretation or overemphasis seems also to be colored by a tendency on the part of these nonclinical health guides to see things, to quote Elbert Hubbard, "as black or white when they are after all but different shades of slaty gray." An unfortunate moralistic tinge seems to vitiate their judgments as to medical and sanitary problems. On these and other questions they seem to train with the decerebrated adrenalin boys. With regard to the x-ray and tuberculosis, for instance, we are told, with agitated table-pounding, that conditions now "cry to high heaven" for the use of the x-ray—a measure that alone will solve the tuberculosis problem in the next decade or two! Tuberculosis societies are suggesting placards and car cards that read: "Have you a health problem—have an x-ray" or "Tell your doctor you want an x-ray." In reality, what conditions call for is a more adequate implementation of the doctor in office or clinic, making possible his full utilization, with intelligence and balance, of the x-ray with other measures, each one of which facilitates, but does not completely simplify, the handling of the tuberculosis problem.

Of course, these exaggerated approaches serve a useful purpose at times. They give us our often unattainable but advantageously motivating slogans. Yet, if overdone, they are apt to lead to public confusion and subsequent letdown.

It may be true that all movements need some stimulation from those unhandicapped by the intricacies and the possibly incapacitat-

ing uncertainties of medicine—such as the lay propagandist or emotional adder of numbers in the medical field. Certainly, they have a reassuring positiveness, an arousing self-confidence, and a conviction of their own rightness not afforded those with a more intimate and complete picture of the complicated clinicopathologic aspects of such a problem as tuberculosis. Indeed, there are those lay executives at work in the medical field, such as our long-time cooperators in the New York State Charities Aid Association, whose non-presumptuous yet able collaboration with the state public health authorities and the State Medical Society has contributed most substantially to the growing conquest of not only tuberculosis but pneumonia, diphtheria, and other problems as well. These lay organizers, promoters, and educators, exercising restrained judgment and initiative, have known how to stimulate medical activity in public health and when to seek medical advice and guidance on things medical.

But such a stimulant must be administered or taken in reasonable and carefully prescribed doses. It must be remembered of the nonclinical mind that it may reach unwarranted conclusions in this field because of ignorance of essential details or lack of awareness of gaps in scientific knowledge. This, no doubt, often accounts for the sometimes hazardous and unwarranted self-assurance. It has been often said that if the average well-trained doctor of medicine could be as sure of any *one thing in medicine* as some of his non-medical or statistical colleagues are regarding *everything in medicine* he would be a most fortunate doctor indeed.

Doctors make poor social promoters. Education of a promotional character is essential to a social or public health program, as is so well illustrated by the New York State experience cited above. Without it we might accomplish little or nothing in community organization. Yet, the promoter must always be protected against his own tendency to grab a conspicuous and new idea and run wild with it. It should always be remembered that the nonmedical man in the medical field has never, after all, heard his professor of medicine orient his class at the beginning of his lecture series by admonishing the embryo physicians that "there are two words that do not appear in the vocabulary of medicine—*never* and *always*."

About 50 per cent of the deaths are due to rupture into the pericardial sac, and the next most common point of rupture is into the left pleural cavity. In certain cases healing takes place,³ and the patients die at a later date of another dissection or from some other cause. The usual course, however, is a spread of the dissecting process with eventual death.

In attempting to decide between dissecting aneurysm with rupture into the pericardial sac and coronary thrombosis, certain points may be listed as being consistent with either diagnosis. These include the negative past history regarding cardiovascular symptoms, the type of pain and associated shock, the fever, and the elevated sedimentation rate. The negative electrocardiogram is not against coronary thrombosis because positive findings are often absent in the first few days of the illness; nor is it against dissecting aneurysm because in this condition electrocardiographic changes are frequently absent. The fact that the heart sounds were of good quality and that the blood pressure was 126/86 is against coronary thrombosis because these findings would be unusual after an attack as severe as this one. These latter findings are perfectly consistent with the diagnosis of dissecting aneurysm. The severe pain immediately preceding the convulsive seizure and the sudden and violent death indicate further dissection with rupture into the pericardial sac producing cardiac tamponade. In making a diagnosis of dissecting aneurysm in this case, it is made in the absence of certain findings, some of which I should like to have found in the history but which are not necessary if the dissection involved only the ascending aorta. These findings are the changing location of the pain, changes in the peripheral circulation, and absence of visceral and lower spinal cord symptoms. I do not consider the elevated blood urea nitrogen or the abnormalities of the urine to be related to the dissecting process. The neurologic signs described are due in my opinion to neurosyphilis of the tabetic type.

The only point remaining is the possibility of the presence of syphilitic aortitis in this case. There are no physical signs of aortitis, such as the presence of a systolic murmur at the aortic area, accentuation of the aortic second sound, or pulsation in the suprasternal notch. However, its presence seems possible because the aorta is frequently affected by syphilis and often without clinical manifestations. About 10 per cent of the reported

cases of dissecting aneurysm had syphilitic aortitis, but the part played in the dissection by syphilis is usually minimized. Aortitis tends rather to sacculization with rupture or, uncommonly, to direct rupture, both of which rarely cause the type of pain described in this case.

Dr. McGrath's Diagnoses

1. Dissecting aneurysm of the aorta with rupture into the pericardial sac.

2. Central nervous system syphilis, tabetic type.

3. Possible syphilitic aortitis.

DR. C. B. WEINBERG: Six months prior to death she had been complaining of pain, nausea, and vomiting nearly every morning.

DR. MCGRATH: What was her blood pressure six months prior to death?

DR. WEINBERG: I did not have the opportunity to examine her.

DR. WRIGHT: Dr. McGrath, would that alter your diagnosis?

DR. MCGRATH: No.

DR. WRIGHT: How long do you think that a patient can live with a dissecting aneurysm?

DR. MCGRATH: Some will repair the dissection and die from other causes. Certain patients have been known to live many months or years after a dissection.

Pathology

DR. MAURICE N. RICHTER: The most important findings are in the aorta. There is syphilitic aortitis with slight aneurysmal dilatation of the arch and marked longitudinal wrinkling of the arch and thoracic portions. There is a ragged tear in the aortic wall 1.5 cm. above the aortic ring, extending in a longitudinal direction and involving all coats. There are about 450 cc. of blood in the pericardial cavity. The heart is not enlarged, and there are no valvular lesions and only slight changes in the coronary arteries.

Two unrelated findings are a small chromophobe adenoma of the hypophysis and the presence of small foci of a peculiar type of fat resembling embryonal fat cells in the bone marrow.

Pathologic Diagnoses

Syphilis of aorta.

Aneurysm of ascending aorta.

Rupture of aortic aneurysm.

Hemopericardium.

Chromophobe adenoma of hypophysis.

DR. WRIGHT: Do you think that the

present; there was no evidence of heart disease which could produce a mural thrombus in the right side of the heart; the physical signs and electrocardiographic findings of pulmonary embolism also were lacking.

I believe the diagnosis in this case lies between dissecting aneurysm of the aorta and coronary thrombosis. A review of the clinical picture of coronary thrombosis appears unnecessary but, because of the renewed interest in dissecting aortic aneurysms, a summary of this condition from the clinical standpoint is pertinent. In the first place, it occurs most frequently between the ages of 40 and 60, but younger people occasionally are victims, as in 1 case² of a young man of 19. It is more frequent in men than in women up to the age of 70, but after that age the incidence is about equal. Hypertension is usually but not invariably present. The onset of pain frequently follows severe exertion. As a rule, the pain is severe and sudden in onset rather than the type commonly seen in coronary thrombosis in which the pain may gradually increase in severity.

The ascending aorta is the commonest site of dissection, and in this situation the pain is precordial and sometimes epigastric. When the aortic arch is the site of dissection, the pain is felt high in the chest; when the dissection involves the descending aorta, the pain is interscapular; and, when the abdominal aorta is involved, pain is located in the lower part of the back and abdomen. As the dissecting process extends along the aorta in either one or both directions, the location of the pain changes correspondingly and this is one of the characteristic findings noted in dissecting aneurysms. Shock is severe and at times there is loss of consciousness, but the latter is not so frequent as it is generally said to be. Nausea and vomiting are common; moderate fever is the rule. Changes in the peripheral circulation develop when the dissection involves certain main branches of the aorta. These are common in the legs, the usual findings being diminished or absent arterial pulsations with a corresponding drop in skin temperature rather than gangrene.

Changes in the circulation of the arms are rather rare as is involvement of the blood supply to the head. However, hemiplegia and convulsive seizures have occurred following interference with the circulation through one of the common carotid arteries. Visceral symptoms follow obstruction of the circulation through the visceral branches of the aorta. Examples are abdominal pain, blood passed by

rectum, hematuria, and diminished renal function. Certain neurologic symptoms develop when intercostal and lumbar arteries are severed or obstructed. These arteries convey in part blood to the lower spinal cord, but an adjustment to the loss of this portion of the circulation is soon made so that the symptoms are usually temporary and varying in nature. Weakness or paralysis of the legs diminished or absent reflexes, and sensory changes are the most common findings. Murmurs occasionally develop in the course of dissecting aneurysm. Their location depends upon the portion of the aorta affected. Systolic murmurs are sometimes heard over the aorta both anteriorly and posteriorly and, occasionally, a diastolic murmur may be detected at the aortic area or along the left sternal border. The latter murmur has two possible causes. One is the production of an incompetent aortic valve by extension of the dissecting process to involve the base of the valve, and the other depends upon the flow of blood through a rent in the intima of the ascending portion of the aorta.

Electrocardiographic changes found in dissecting aneurysm are of two types. The direct type results from a nonfatal small rupture into the pericardial sac with hemo-pericardium or from extension of the dissection into one or both coronary arteries. The changes due to hemo-pericardium usually consist of negative T waves in all leads, while those resulting from reduction in the coronary circulation resemble the changes seen in coronary thrombosis. The indirect type of electrocardiographic changes is less distinct and results from the effect of shock on an already impaired coronary circulation. This is often present in patients who develop a dissecting aneurysm.

X-ray examination is an important diagnostic measure but is rarely done because the patient is so seriously ill. When the dissection involves a portion that can be visualized, x-ray will frequently show an abnormality of the aorta and a series of daily pictures will reveal a progressive enlargement of the aorta. Leukocytosis is common within a few hours. Increased sedimentation rate develops in a day or two, and somewhat later an elevated icteric index and a secondary anemia may be found.

Except during shock or when dissection directly affects the heart, as mentioned under the discussion of electrocardiographic changes, the heart is not altered. Recovery from shock in the nonfatal cases is accompanied by a return of the blood pressure to its usual level.

Uterine Tumor of Endometrial Stroma Type. Dr. Chester R. Brown and Dr. Amour F. Liber

There exists a primary neoplasm of the uterus consisting of tissue strongly resembling, not identical with, the endometrial stroma and apparently growing from it. Three different interpretations and names have been assigned to this type of growth: (1) Typical endometrial sarcoma (Meyer, R.: *Handbuch der Speziellen pathologischen Anatomie*, vol. II/1, 1930); (2) adenomyoma without glands (Casler: *Tr. Am. Gynec. Soc.* 44: 68 1919); (3) endolymphatic fibromyositis (Frank: *Am. J. Cancer* 16: 1326, 1932). To judge from the small number of cases reported, the neoplasm in question is extremely rare. No adequate information is available as to the life history, prognosis, and therapeutic indications, although the tumor is morphologically extremely distinctive and readily identified.

Case Report

A 46-year-old woman was admitted to the gynecologic division of Lincoln Hospital. She complained of menstrual pain of three years' duration, metrorrhagia and dysuria for three months and, finally, of the appearance of a suprapubic mass increasing rapidly in size. The finding of a corpus uteri diffusely enlarged to the size of a grapefruit led to the diagnosis of myomatous uterus. Subtotal hysterectomy and unilateral removal of the adnexa were performed.

Gross examination showed diffuse and symmetric thickening of the uterine wall with no discrete tumor nodules. Many small polypi projected into the cavity of the corpus. In the left tube and round ligament were seen several small nodules.

On microscopic examination throughout the endometrium were columns of tissue resembling in every respect the stroma of the endometrium and forming an anastomosing network. In several places this newly formed tissue was continuous with the distinctly hy-

perplastic stroma of the endometrium. High-power magnifications showed the neoplastic tissue to be made up of small, rounded, slightly elongated or occasionally branching cells containing a small amount of cytoplasm surrounding a nucleus with a distinct, thin, nuclear membrane and diffuse, finely granular chromatin. Each cell occupied a mesh of a fine network of argyrophilic reticulin. Numerous small blood vessels were formed directly by the tumor tissue. Here and there throughout the neoplasm were large empty spaces lined only with flattened endothelium, into which rounded masses of tumor projected. These were, in all probability, lymphatic vessels. The tube and round ligament contained round masses of the neoplasm entirely within greatly dilated vessels, some of which contained blood and appeared to be veins while others were apparently lymphatics.

The patient was followed for three years after operation, after which she was lost sight of. She received radiotherapy in another institution. When last seen she had a large, and still growing, mass in the right lower quadrant of the abdomen.

This case illustrates the rare type of growth which apparently arises from the stroma of the endometrium and faithfully reproduces its structure. In spite of the lack of histologic atypism, the tumor has a certain tendency to invasion of the uterus and, in this case, of the adnexa. While the exact oncologic classification of the neoplasm is still open to question, the present case shows that for practical purposes it must be regarded as having some of the features of malignancy.

Discussion

DR. NICHOLAS M. ALTER: I should like to report 2 fatal cases, 1 of which died four days after operation. At the time of operation a hysterectomy was performed for bleeding.

adenoma of the pituitary had anything to do with the inequality of the pupils?

DR. RICHTER: The adenoma is too small to have caused pressure symptoms.

DR. WRIGHT: What do you think was the immediate cause of death—the pressure on the heart brought about by the hemorrhage or the loss of blood?

DR. RICHTER: I think that it was caused by the rise of intrapericardial pressure resulting from the hemorrhage.

Prize Essays

THE Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, April 27, 1942, in New York City.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the Prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win the prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1942, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York.

CHAS. GORDON HEYD, M.D., *Chairman*
Committee on Prize Essays

NATIONAL SOCIAL HYGIENE DAY

Wednesday, February 4, will be the Sixth National Social Hygiene Day, to be observed throughout the country. The purpose of this annual event is to maintain and strengthen public interest in the fight against syphilis and gonorrhea and conditions favoring their spread. That fight was never more important than it is in this time of national emergency, when the health and welfare of young men being called up for military service is giving all of us concern.

rhea and conditions favoring their spread. That fight was never more important than it is in this time of national emergency, when the health and welfare of young men being called up for military service is giving all of us concern.

ribbon, occasionally only on one edge. Cross and longitudinal striations occurred only in parts of the ribbon, the remainder of which was granular. Meyer interpreted this as regressive phenomena with striations breaking down into granules or "schollen." Within a single muscle bundle he saw "myoblasts," transition forms, normal muscle fibers, and no evidence that the myoblasts invaded the bundle from without. Finally, incipient changes in the direction of "myoblasts," such as small areas of granular cytoplasm, were seen in otherwise normal muscle fibers near the "growth."

This case is significant because of its age, and Meyer believed that it refuted the theory that striations appear as progressive differentiation in myoblasts. Abrikossoff's cases were advanced, and it was impossible to tell in which direction the change was taking place (Meyer). Meyer believed that diffuse granular swelling of the cells of the tumor plus occasional large cells explained the size of the nodule, even though cell multiplication was slight, and that various combinations of degeneration, regeneration, hyperplasia, and tumor formation existed in some cases of myoblastoma.

This author studied a tumor developing in the rectus abdominis, six years after ventral fixation of the uterus, in a case of endometriosis. There was marked regenerative hyperplasia of the striated muscle with "myoblasts" showing fatty degeneration and "apparent

multiplication of the nuclei which could easily be mistaken for cellular proliferation . . . the multinucleate structures reproduce themselves but do not differentiate into striated fibers."

Klinge, in 1928, postulated a dysontogenetic origin for myoblastoma arising in locations normally devoid of striated muscle (skin, mucosa). In these tumors the granular cells do not resemble any normal embryonal stage of muscle development, a further reason for doubting the maturation of myoblasts to muscle fibers in the lingual nodules (Meyer).

The tumor may exist for long periods. Klemperer's series included a tumor of the groin existent for twenty years and another existent in the right calf for twelve years. Only 3 recurrences have been recorded. Seventy-seven cases were reported in 1934 (Grey and Grunnfeld); 34 had tumors in the tongue.

Klemperer stated that cells of myoblastoma "may suggest the diagnosis of xanthoma and differential diagnosis rests upon the presence or absence of fat within the tumor cells."

Fat is present in certain instances of degenerating voluntary muscle and possibly in some cases of "myoblastoma" which are derived from degenerating voluntary muscle. Granular myoblastomas do not form striated fibers. The histologic picture may present various degrees of degeneration, regeneration, hyperplasia, and neoplastic-like changes. Recurrences represent further areas of degeneration and hyperplasia following repeated trauma, which was most likely in our case.

Infections with Organisms of the Salmonella Group. Dr. Siegbert Bornstein (by invitation).

The methods of isolation and identification of those organisms that formerly were referred to as the paratyphoid-enteritidis group and nowadays are called "salmonella" have been considerably improved during the past ten years. Consequently, the number of known separate species within this group has increased to almost a hundred, and our conceptions of the importance of these organisms for human pathology have undergone certain changes. A renewed study of salmonella infections, based on material examined by modern methods, seems necessary.

On 500 human salmonella infections in North America and Cuba serologic type determination was carried out. Thirty-two types were represented; fifteen of them can be considered as rare. The large number of known types makes it necessary to have many serums and type cultures at hand. This has pre-

vented the serologic type diagnosis from becoming widely used. Many laboratories still only recognize *Salmonella paratyphi A*, *S. paratyphi B* (Schottmueller), *Salmonella typhi murium* (= aertrycke), *S. cholerae suis* (= supestifer), and *Salmonella enteritidis* (Gaertner), and record the others as "unclassified salmonellas." This puts more than one-third of the causative organisms of human salmonella infections together with bacteria of questionable pathogenicity. A simplified method of recognizing the seventeen outstanding types will be suggested in a forthcoming publication.

Several types formerly reported to have been found in animals only were recently isolated from man. Multiple infections were observed. Hormaeche, in Montevideo, cultured from 1 child five different salmonella types.

Clinical information was available in 369 of

The case was clinically diagnosed as myoma of the uterus and, when I received the uterus, there was a uniform layer $\frac{1}{2}$ inch in thickness of gray-white, medullary type of tissue, sharply limited, which on microscopic section

seemed to be similar to Robert Meyer's description. At the time of operation it was reported that there were other pelvic masses.

In the other case there were extensive metastases to the ovary.

Myoblastoma of Striated Muscle with Brown and Dr. Amour F. Liber

There exists a benign tumor of striated muscle first mentioned by Heurteaux in 1881. Abrikossoff in 1926 designated the tumor "myoblastic myoma." An atypical tumor of this type was removed at Lincoln Hospital.

J. H., a 60-year-old white man, was admitted to Lincoln Hospital on July 4, 1941, for treatment of an "ulcer of the left leg." The present illness began in 1931 when the patient noticed a small, painless, marble-sized mass in the calf of the left leg gradually increasing in size. This was removed at a New York hospital in October, 1931. The mass was described "as 4 cm. in diameter, encapsulated, and rubbery." The microscopic diagnosis was spindle-cell sarcoma. The patient received heavy treatments with x-ray following excision. Three months later the wound "broke down" and a small ulcer formed locally.

In 1932, at another institution, a biopsy was performed and a diagnosis of spindle-cell sarcoma made. The patient was again treated with x-ray and radium and was discharged with a draining sinus, which has persisted since 1932 to the present admission. At the time of discharge in 1932, the patient stated that he felt a small nodule in the calf of the leg which has enlarged considerably in past years.

Clinical Examination.—"On the calf of the left leg was an area of heaped-up granulation tissue and a draining sinus in the center. This area measured 4 by 8 cm. The surrounding tissues were considerably indurated." Local excision of this area was performed. "The fascia covering the soleus muscle was infiltrated with what appears to be neoplastic tissue extending from just below the popliteal space to about 3 inches from the heel."

Marked scarring and induration of the fascia and muscle layer were noted extending down to the upper portion of the fibula. There was a foreign body $\frac{1}{2}$ inch in length found centrally located within the indurated areas which resembled a Radon seed.

About ten to fifteen small, firm pieces of tissue were submitted to the laboratory. Mi-

Lipid-Containing Cells. Dr. Chester R.

croscopic examination revealed areas of degenerating striated muscle adjacent to diffuse neoplastic-like cellular infiltrations. These cells showed finely granular cytoplasm with numerous monorefringent, coarse brown granules staining red with scharlach R, and one or more rounded, central, or eccentric nuclei. Transitional forms showing persistent striations and large rounded eosinophilic globules occurred between the degenerating muscle and granular tumor cells. The latter apparently were derived from degenerating striated fibers. Microscopic diagnosis was atypical granular-cell myoblastoma.

All authors agree that Abrikossoff's typical myoblasts stain negatively for fat. Considerable doubt exists regarding the pathogenesis of myoblastoma. There are three current opinions:

The tumor represents a regeneration of striated muscle following injury (especially in the tongue) with hyperplasia (Abrikossoff, Meyer) and neoplasia (Diss) of striated fibers. Abrikossoff described a tumor derived from voluntary muscle and composed of cells termed "myoblasts," polygonal-shaped, with granular cytoplasm, showing syncytial prolongations, some of which revealed striations. He compared this cell to the embryonal myoblast and believed that transitional forms showing striations were at times formed by the granular myoblasts. The tumors were found in various portions of the body and in situations where no striated muscle normally existed.

Meyer, in 1932, agreed that injury probably preceded tumor formation in some cases (in the tongue, especially) but stated that myoblasts showing striations were remnants of degenerating striated cells as were the granular forms. He denied that Abrikossoff's myoblasts could form new muscle fibers. A small growth in the tongue (Meyer) was first noted three weeks prior to removal. Although transitions were noted between striated and unstriated cells, these did not occur as in young muscle cells—i.e., as longitudinal striations in narrow elongated cells—but irregularly, in various portions of the muscular

ent strains of the same serologic salmonella type.

In conclusion, it can be said that seventeen salmonella types are of major importance for human pathology in this country. They should be generally recognized. It would be of diagnostic advantage to include a few of the more important salmonella antigens in the Widal reaction. There is no principal difference between paratyphoid fever in a stricter sense and other salmonella infections. Salmonella septicemia is not a rare disease; it has a high lethality. The salmonella carrier state involves danger of distribution as well as danger of septic infection for the carrier himself. Types that were only known to occur in animals were recently found in man. More research is necessary to establish a classification of salmonellas according to their pathogenicity and invasiveness.

Discussion

DR. AMOUR F. LIBER: I should like to ask Dr. Bornstein if a salmonella that is really nonpathogenic to man (if this may be assumed for any of these organisms) were ingested—as, for example, *Salmonella pullorum* ingested accidentally or by the eating of raw eggs which happen to be infested—would the organism still be viable in human feces? In a laboratory that is not equipped to do serologic tests but can only approximate the diagnosis by cultural methods, would it be necessary to take into consideration such a possibility?

DR. ALFRED ANGRIST: The statement that Dr. Bornstein made about the incidence and frequency of these organisms is borne out when atypical coli and the like are tracked down. In the last few years we have been successful in isolating at least six or more of these strains. The case that Dr. Bornstein referred to which came to autopsy with a typhi murium infection, if I am not mistaken, represents the only typhi murium case that came to autopsy with enteric lesions resembling those of typhoid fever. The resemblance to typhoid fever was rather striking, both in the gross and in the microscopic pictures. I should say, for the record, that the autopsy was not performed by myself but by Dr. Mitchell, and the organism was not isolated by myself but by our bacteriologist, Miss Wollov. In that sense, I am almost an ideal discussor, having had so little to do with the case. The findings on autopsy suggested a lesion resembling typhoid. The microscopic lesions showed all the characteristic cells with the large mononuclear cells

prominent throughout the lymphoid tissue, particularly in the ileum, in Peyer's patches, and in the colon, rather more extensively than is seen in the typhoid group of infections. The spleen was not markedly enlarged. That was another feature that Dr. Bornstein stressed.

The Peyer's patches were quite hemorrhagic. Some superficial ulcerations occurred, but the entire Peyer's patch was seldom ulcerated. There was no marked hyperplasia of the lymphoid tissue in the colon, but there were numerous small ulcerations and an occasional large ulcer.

Microscopically, the Peyer's patches were seen to be edematous and to contain the rather characteristic large mononuclear cells in great numbers. The patient had a peritonitis, and many of the cells in the fibrinopurulent exudate on the peritoneal surface were of this same type. The lymph nodes also were filled with the large mononuclear cells. The liver did not show any focal necrosis but did show extensive portal infiltration, and there was a diffuse myeloid reaction throughout.

We took the culture material and also some of the material from other strains of salmonella and injected nine guinea pigs and six mice and rats with the organism. We were quite fortunate, I think, in obtaining spectacular lesions. Most of the animals lived beyond the third or fourth day. Many of them lived for two weeks and then the batch was killed. The changes in the Peyer's patches in the guinea pigs consisted of extensive infiltration with exudate and abscesses filling some of the deep glands and the characteristic mononuclear type of infiltration. There was some typical focal necrosis throughout the liver. There was also a diffuse myeloid reaction in this tissue. The lymph nodes showed extensive focal necrosis and a prominent exudate of large mononuclear cells.

The clinical record of this case presented a young man, 21 years of age, admitted with a picture of acute appendicitis, with the story of having felt well until twenty-four hours before admission, when he had a sudden abdominal pain with nausea and vomiting. The pain settled in the right lower quadrant three to four hours before operation. Operation showed a normal appendix, but we noted a periappendiceal exudate on microscopic study. The ileum was found to be rather turgid and edematous. The patient developed peritonitis and lived three or four days postoperatively.

our cases. Thirty-four, or almost 10 per cent of our cultures, came from healthy persons, some known to be contacts, some not. Seventeen of these cultures belong in the serologic group C, whose main representative is *Salmonella cholerae suis*. *S. typhi murium*, which otherwise represents almost one-third of our material, was cultured from healthy persons only twice. We have observed carriers for periods up to eight months. They are not only a possible source of transmission but are in danger themselves, because occasionally the organisms enter the blood stream and may get a foothold at a site of lowered resistance.

In 49 of our cases the clinical disease was septicemia, which means that the outstanding feature was the presence of the bacteria in the blood or parenteral foci of infection. The diagnoses were septicemia, endocarditis, abscess, osteomyelitis, pleurisy, peritonitis, meningitis, and others. The organisms belonged thirty-five times in group C. Among the others were *S. enteritidis*, cultured from the spinal fluid in a case of fatal meningitis and *S. typhi murium* from an osteomyelitic focus and from the peritoneum of a child with peritonitis. There were 18 deaths in this group. Though no lethality statistics can be deduced from our material, the high incidence of septic infections, their high death rate, and the findings of salmonellas of groups other than C is noteworthy.

The histology of septic infections with salmonellas, so far as we know, is not in any way characteristic. In the case of a woman typhoid carrier who had a twisted ovarian cystoma, Dr. Plaut found the peritoneal layers entirely formed by typhoid cells. The specific histology in this case is no reason to see a fundamental difference between it and a salmonella peritonitis. The typhoid bacillus also causes changes without typical histology, like the so-called gastroenteritis typhosa, and purulent lesions and, on the other hand, various salmonellas can produce typhoid-like anatomic lesions.

Another group of diseases caused by salmonella infection is that of enteric fever, similar to the mitigated or atypical picture of typhoid fever often seen in children. Leukopenia and slow pulse rate may or may not be present; roseola and splenic enlargement seem to be mostly absent. Fifty-one such cases were in our series, 1 with *S. paratyphi A*, 25 with *S. paratyphi B*, and also 25 others. In this type of infection it is necessary to include a few of the more important salmonella

antigens in the Widal reaction, otherwise diagnoses may be missed or wrongly interpreted. Dr. Angrist has performed the autopsy on 1 case in this group, which was due to *S. typhi murium*, and found a typhoid-like anatomic picture. In all, there were 5 deaths in this group.

The remaining 235 patients had gastroenteritis, often called "food poisoning." All serologic groups of salmonella were found responsible for this disease, including *S. paratyphi B* in 12 of our cases. *S. typhi murium* occurring in 94 patients is outstanding in this group. Five of these patients died—2 of these were infants and in 2 cases the salmonella infection was only a contributing cause of death. The gastroenteritis cases, which are the most frequent but not the only clinical manifestation, have caused the belief that salmonella infections in general have a low mortality.

Though certain types of salmonella cause one or the other clinical picture more often, all may cause either septicemia or enteric fever or gastroenteritis. The same conditions may be due to the typhoid bacillus, which serologically belongs in the salmonella group and which causes anatomic and histologic changes that also may be caused by other salmonellas.

The same serologic type may be the cause of outbreaks in which the clinical manifestations are rather uniform, but in one outbreak it may be enteric fever, in the other, gastroenteritis. This makes one believe that there must be differences in the condition of strains of the same type which are responsible for the degree of pathogenicity and invasiveness. A classification of salmonellas in this respect is needed.

Sulfaguanidine is strongly bacteriostatic for *S. cholerae suis* and fairly so for *S. paratyphi A*, while other salmonellas are resistant to the drug. Differences in resistance against alpha-methyl-d-galacturonate were recently reported to exist between salmonellas by Steinhäus and Georgi. Such differences may not only give helpful hints for the treatment of infections but may possibly permit the formation of groups that fit the epidemiologic facts better than the serologic groups do.

Another classification whose relation to pathogenicity needs further study is the division of salmonella strains into those that we have called "potentially hemolytic" and others. The typhoid bacillus contains a sheep-hemolysin that can be liberated from the bacterial cell by bacteriophages. Such hemolysin may be present or absent in differ-

palpable in the left axilla; there was no other extension in the body. On January 31, 1940, the left breast was practically clear and the left axillary nodes were palpable. The blood count was practically unchanged. The blood chemistry was normal. There was no involvement of other organs. On February 14, 1940, there was spontaneous delivery of a healthy male infant, weighing 3,730 Gm. Three weeks after delivery the patient was readmitted with pain along the spinal column. An x-ray examination showed no bone or chest involvement. In March, four months after first being seen, the patient's temperature became septic, she had marked diaphoresis, and on March 21 she began to have black stools and nosebleed. She died April 3.

Autopsy revealed a large tumor mass about 20 cm. in diameter replacing the left breast. The right breast was normal. Both axillas, neck, and inguinal regions showed discrete lymph nodes from 0.5 to 2 cm. in diameter. In the retromediastinum there was a small mass of lymph nodes matted together measuring 5 by 3 by 1.5 cm. The heart and lungs were normal. In the retroperitoneum there were about ten lymph nodes from 1 to 4 cm. in diameter. The liver weighed 2,300 Gm. and showed circumscribed and diffuse white metastatic nodules. The spleen weighed 550 Gm., was diffuse and firm, and had no nodules. Each kidney weighed 250 Gm. and showed tumor nodules. The gastrointestinal tract showed several nodules 0.5 to 1 cm. in diameter in the lower ileum; one larger nodule had perforated to the mucosa. There was diffuse peritonitis, 300 cc. of exudate being present. Culture of the peritoneal fluid yielded *Bacillus coli*.

Microscopic examination of the breast revealed mixed types of lymphocytes in many areas still reticular in type with large pale nuclei. Silver stains showed similar variation from short thick bundles to fine fibrillar network. The veins contained tumor thrombi. Sections of the nodules in the liver and kidney showed mostly small dark lymphocytes of the differentiated type, silver stain showing fine network. The liver and kidney also showed diffuse infiltration as seen in leukemia. The lymph nodes from various sites showed variations from the large, pale cell, reticular type to the mixed variety with small dark cells.

Case 2.—Mrs. S. A., a 43-year-old white woman, P 3, complained of soreness and heaviness of the abdomen. The menstrual periods had been regular with a slight excess of flow. A laparotomy was performed six weeks

after the patient was first seen; she had lost 15 pounds in the past six weeks, had become weaker, and the skin had changed to a light lemon color. Operation showed bilateral encapsulated ovarian tumors, with multiple small nodules in the liver, omentum, and enlarged retroperitoneal nodes.

The gross specimen consisted of a right ovarian tumor measuring 14 by 11 by 10 cm. and a left ovarian tumor 10 by 6 by 6 cm., both encapsulated. On cross section they were similar, showing diffuse whitish gray growth with irregular areas of hemorrhage and necrosis.

Microscopic examination showed a new growth of small round cells almost syncytial, with large pale nuclei and with fibrous stroma around the capsule, otherwise, coarse reticular fibrils. The patient did not recover from the operation and died after fourteen days; autopsy was not performed.

The first case has clinical, gross, and microscopic evidence of generalized lymphosarcomatosis, which started in the left breast; the primary site in the breast showed reticular sarcoma. The metastasis was of blastomatous nature. Hematogenous nodules were, however, in most places of the mature lymphocytic type. Primary autochthonous development was observed in lymph nodes, particularly of the retromediastinum and retroperitoneum, which were also reticular in type.

The second case demonstrated a rare type of tumor of rapid malignancy which probably originated in the right ovary. The operative findings and the histologic picture are the only evidence, since no autopsy was performed. Subdivision of sarcomas of lymphoid tissue seems inadvisable, since various types from the most undifferentiated syncytial or reticular types to the mature lymphocytic type can be found in the same case and probably represent various stages of histogenesis.

Conclusions

Two cases of lymphosarcomas are presented with unusual primary sites, one in the breast and one in the ovary.

The primary site of both cases presented a typical histologic picture of reticular sarcoma.

The terminal condition of the breast case at autopsy was that of generalized lymphosarcomatosis, with hematogenous and lymphatic metastases in the viscera and lymph nodes consisting of lymphoblasts at various stages of differentiation. Some lymph nodes,

We recovered a typhi murium from the stool clinically and from a colonic ulcer, as well as a typhi murium and a hemolytic streptococcus from the peritoneum at autopsy. I think another unusual feature was that the patient had a low white count, about 2,100 on admission. Other than that, his picture was typical of appendicitis.

DR. LEO MEYER: During the summer of 1940 there was an epidemic of food poisoning in Brooklyn, during which 40 people were infected with the aertrycke bacillus, which was identified by the Health Department. They had eaten some smoked fish, and within six hours all had developed severe gastroenteritis. Two of these people died, and I autopsied 1 of them. This was a 40-year-old man who lived for four days. He had a green mucoid cast of his entire small intestine, which was adherent to Peyer's patches, and the curious thing was that histologic section through these showed a nonspecific ulceration and did not demonstrate the large mononuclear cells that Dr. Angrist showed. There were positive blood cultures, and cultures from the spleen and mesenteric nodes also revealed the same organism.

The second case was also in an adult who had eaten smoked fish from the same source two weeks previously, and this person had no evidence of ulceration of the intestinal tract. At postmortem the only diagnosis was bronchopneumonia with sepsis, and the organism was recovered from the blood stream.

I should like to ask Dr. Bornstein if he considers the aertrycke bacillus the same as typhi murium. Some of the textbooks separate them; some do not.

DR. ANGRIST: There is another point I wish to stress. In some work with pneumococcus and the effects of sulfapyridine, we have been rather unsuccessful in the determination of virulence, if that is any indication of what can be hoped for in a similar reaction with similar agents on the part of typhi murium. We have recovered both sulfapyridine-fast and nonfast strains both from autopsy material and from clinical material showing recovery. I do not know if that will carry over to the salmonella group.

DR. SIEGBERT BORNSTEIN: *Bacillus aertrycke* and *S. typhi murium* are synonymous.

To answer Dr. Liber's question, may I say I do not know what would happen to a man who swallows *Salmonella gallinarum*. I would not advise anyone to do it because he might become the first case of such an infection, as was that veterinarian who did not think that *Salmonella abortus equi* was pathogenic for man and was not careful. He got pretty sick. We know what happens to animals when they are fed with typhoid bacilli, which are not pathogenic for them—nothing happens, the organisms disappear quickly from the animal, and so, I suppose, would *S. gallinarum* from man.

I wish to thank Dr. Angrist for his support and to express my gratitude to the Society for the opportunity of presenting this work here, because even though these results are modest and unfinished, we think they are a challenge for a renewed study of salmonella infections based on the newer knowledge of the organisms. For such work our group needs the support of as many pathologists as possible.

Lymphosarcoma with Special Reference to the Original Site (Report of 2 cases (1) Breast and (2) Ovarian). Dr. Nicholas Alter.

The terminal condition of lymphosarcoma presents an almost impossible problem as to the original site. For such work two requirements are necessary: careful clinical observation, to trace the development of the pathology, and gross and histologic studies. Two cases are presented with special consideration to the above requirements.

Case 1.—Mrs. M. C., a 32-year-old white woman, was admitted in the twentieth week of her third pregnancy (November 3, 1939). The left breast was twice the size of the right; the mass was diffuse; there was tenderness over multiple skin nodules and particularly over the nipple. No axillary nodules were felt.

The right breast had been entirely negative. The patient was under observation for one month. Blood counts were negative. The white cells ranged from 7,000 to 8,000, and lymphocytes were never higher than 10 per cent. A biopsy of the skin nodule was diagnosed as sarcoma of the breast. This was followed by deep x-ray therapy. During this stay at the hospital there was no evidence of extension of the disease; the liver and spleen were not enlarged or palpable. There were no complaints relating to any of the organs. The patient was readmitted seven weeks after first being seen. The skin nodules had disappeared, but discrete lymph nodes were

Medical News

1942 Registration Certificates

Information has come from Dr. Joseph S. Lawrence, executive officer, that the Department of Education is doing its utmost to supply the physicians with their 1942 registration certificates but has been greatly delayed, first by the installation of new recording machines and now by a lack of clerical service.

Physicians who have applied for re-registration are assured that they will receive their certificates at an early date, and in the meantime they need not fear that they are violating the law by continuing their practice.

County News

Chautauqua County

Dr. George W. Cottis has been appointed chief of the emergency medical corps for Jamestown. Dr. Cottis, who is president-elect of the New York State Medical Society, was a Medical Corps Captain during the first World War and served overseas.

Chenango County

At the annual meeting of the county society held December 9 the following officers were elected for 1942: president, Dr. Ben Lee Dodge, Bainbridge; vice-president, Dr. William Perry Elliott, New Berlin; secretary and treasurer, Dr. John H. Stewart, Norwich; censor of three years, Dr. Leslie T. Kinney, Norwich; delegate to State Society, Dr. Archibald K. Benedict, Sherburne.

The committee chairmen are: legislative, Dr. Jaynes Mott Crumb, South Otselec; public health, Dr. Edwin Fred Gibson, Norwich; economics, Dr. Norman Campbell Lyster, Norwich; maternal welfare, Dr. Carl D. Meacham, Greene. Dr. Heinz Gunther Cohn, of Afton, was elected to membership.—*John H. Stewart, M.D., Secretary.*

Members of the Chenango County Medical Association were guests of the Rotary Club in Norwich on December 9. Dr. John H. Stewart introduced the following: Drs. J. C. Boland and R. M. Vincent, of Binghamton; Dr. Ben Lee Dodge, of Bainbridge; Dr. Archibald K. Benedict, of Sherburne; Dr. Jaynes Mott Crumb, of South Otselec; Dr. A. H. Evans, of Guilford; Drs. William D. Mayhew and M. G. Boname, of Oxford; Dr. Carl D. Meacham, of Greene; Drs. William Perry Elliott and E. A. Hammond, of New Berlin; Drs. M. H. Jacobi and L. T. Kinney, of Norwich.

Essex County

The following officers were elected at the annual meeting of the society held in Ticonderoga: president, Dr. Albert Leonard Hayes, Willsboro; vice-president, Dr. Samuel A. Volpert, Lake Placid; secretary-treasurer, Dr. James Edward Glavin, Port Henry; censors, Dr. John Sanders Miller, Jr., Crown Point, Dr. John Breen, Schroon Lake, Dr. Thomas J. Cummins, Mineville; delegate to the state convention, Dr.

Joseph A. Geis, Lake Placid; alternate, Dr. Thomas R. Cummins, Ticonderoga, delegate to Fourth District Branch, Dr. George Le Roy Knapp, Ticonderoga; alternate, Dr. Edwin C. Johnson, Newcomb.—*James E. Glavin, M.D., Secretary.*

Fulton County

Members of the county society, at a dinner meeting on December 17, paid tribute to Dr. John D. Vedder, of Johnstown, highly respected member and officer of the society for many years.

At the business meeting held during the evening the following new officers were elected: president, Dr. Arthur R. Wilsey, of Gloversville; vice-president, Dr. Herbert C. Hageman, of Gloversville; secretary, Dr. Louis Tremante, of Gloversville; treasurer, Dr. D. Malcolm McMartin, of Johnstown.

Dr. B. A. Winne, of Johnstown, retiring president, presided over the after-dinner program. Seated at the speakers' table were Drs. B. G. McKillip, Vedder, Winne, George Lenz, Tremante, and Arthur C. Hagedorn.

Genesee County

Dr. Raymond L. Warn, of Oakfield, will head the county society during the coming year. He was elected at a meeting at the Batavia Club on December 11 when Dr. Robert G. Wilson, of Batavia, became vice-president and Dr. Peter J. Di Natale, of Batavia, was renamed secretary and treasurer. Dr. Di Natale will also be the delegate to the New York State Medical Society Annual Meeting and Dr. Paul P. Welsh, of Le Roy, will be the alternate delegate.

The county medical society announced on December 16 a new schedule of fees for home and office calls, the change being attributed to "cost of medical materials and supplies and operating expenses increasing to a considerable degree."

The basic minimum charge for office attention is listed at \$2.00. The remainder of the new schedule is as follows: \$2.50 for home visit between the hours of 7:00 A.M. and 7:00 P.M., \$3.00 for a home call between 7:00 P.M. and midnight, and \$4.00 for a home call between midnight and 7:00 A.M.

An additional provision of 50 cents a mile for calls outside the city or village limits is made.

particularly in the retroperitoneum and retro-mediastinum, reproduced a reticular, undifferentiated type.

Clinical and histologic studies were necessary to ascertain the primary site showing the reticular type of growth. In the case of generalized lymphosarcomatosis, the lymph nodes

showed also autochthonous growth as in the original site.

In the hematogenous and lymphatic metastases, lymphosarcoma behaves as any other malignant growth.

The case of ovarian growth was entirely blastomatous in nature.

"What Must We Do to Improve the Health and Well-Being of the American People?"

The next few months will be vital ones in the life of our nation. Are the American people ready to meet the demands that will be made of them? Although our living standards are higher than those of any other country, there is yet much that needs to be done to make our people physically, mentally, and spiritually fit—fit to meet the challenge that Totalitarianism has hurled at the Democratic way of life. What must we do to improve the health and the social, economic, and spiritual well-being of the American people? Surely we must give thought at this time to our internal as well as to our external defenses.

In order to encourage you to express your thoughts on this important topic, Town Hall, through the generosity of a member of its Board of Trustees, Mr. Russell Maguire, offers \$1,000 in cash prizes for the best essay on the subject.

The prizes are divided into two sets: one set for the best essays written by any contestants 21 years and over, and the second set to go to the best essays by any contestants under 21 years. There will be two first prizes of \$250 each—one in each age group, two second prizes of \$100 each, two third prizes of \$50 each, and ten prizes of \$10 each in each age group. The two first-prize winners will also be given a trip to New York, or any other city from which "America's Town Meeting of the Air" may be originating at the time of the award, and will be presented on the broadcast.

Rules of the Contest

Please Read the Rules Carefully

1. Essays are not to exceed 1,000 words in length.
2. Envelopes containing essays must be postmarked not later than February 1, 1942.
3. All essays submitted become and remain the property of Town Hall, and any essay may be used in *Town Meeting* or in other publications at the discretion of Town Hall.
4. The essays will be judged by a committee of prominent Americans selected by the Board of Trustees of Town Hall. Their decisions will be final.
5. Essays will be judged on the basis of originality, practicality and clarity.
6. Everyone is eligible to participate in this contest in his own age group, except persons connected with Town Hall or the National Broadcasting Company and their immediate families.
7. Essays should be written on one side of paper—and typed if possible.
8. *Be sure to indicate on your essay whether you are entering the contest in the Adult or Youth Divisions.*
9. Winners will be announced as soon as possible after closing date of February 1, 1942.

Mail Essays to: ESSAY CONTEST EDITOR, Town Hall, 123 West 43rd Street, New York, N. Y.

Convalescent: "The touch of the nurse's hand cooled my fever instantly."

Doctor: "Yes, I heard the slap away down the hall."
—*The Canadian Doctor*

Auntie: "And what will you do, my little darling, when you grow up to be a great big girl?"

Child: "Reduce."

—*Selected*

At the afternoon session Dr. James S. Edlin, New York City, will be the chairman.

2:30—"The Role of the Radiologist in the Diagnosis of Diseases of the Chest," by Dr. Henry K. Taylor, Director Department of Radiology, Welfare Hospital, New York City.

Discussion opened by Dr. Bart R. Young, Associate Professor of Radiology, Temple University Medical School and Assistant Director, Department of Radiology, Temple University Hospital, Philadelphia, Pa.

4:00—Chest X-Ray Conference

4:30—Business Meeting

Onondaga County

Dr. George S. Reed was elected president of the Syracuse Academy of Medicine at the annual meeting on December 16 held at the University Club. Dr. J. G. Fred Hiss was chosen vice-president.

Also elected were Dr. George C. Goewey, secretary; Dr. William E. Pelow, treasurer; Dr. M. G. Brown, trustee for a three-year term; and Drs. Noble R. Chambers, Gerald C. Cooney, and Ferdinand J. Schoeneck, members of the council.

Orange County

Dr. William T. Lemmon, assistant professor of surgery at Jefferson Medical College Hospital and attending surgeon at Philadelphia General Hospital, spoke before the general staff meeting of Horton Memorial Hospital on December 17 on "Continuous Spinal Anesthesia." He showed slides and moving pictures in color of the technic and uses of this method of spinal anesthesia.

Queens County

On Tuesday, January 27, Dr. Frank H. Lahey will be the guest of honor of the society at a dinner at the Forest Hills Inn. At 8:00 p.m. the same evening, a kodachrome motion picture from the Lahey Clinic entitled "Subtotal Thyroidectomy" will be shown in the society's Auditorium. Following this, Dr. Lahey will speak on "Newer Developments in Surgery."

Rensselaer County

Dr. A. J. Hambrook has been appointed medical consultant in the Troy Department of Public Welfare, a new position provided for in the 1942 city budget.

Dr. Hambrook assumed the post on January 1. The new position is required by the state as a part of the new unified medical care program being installed in the city department. The new state policy by which local welfare agencies will set up and administer their own medical care programs, instead of operating under the centralized State Medical Manual, is the result of extended conferences between the State Department of Social Welfare and the State Medical Society.

Dr. Russell B. Scobie, of Newburgh, discussed "Medical Problems and Care of the Pre-School Child" at a meeting on December 18 at the Troy Health Center.

This was the first of a series of seminars in pediatrics held in connection with the newly

organized Child Health Service in rural Rensselaer County.

Present at the meeting were Dr. Elizabeth Gardener, director, Department of Maternity Infancy and Child Hygiene; Dr. Helen Owens, assistant director; and Dr. F. E. Coughlin, district state health officer. Dr. John Sibbald, president of the county society, presided. The discussion was opened by Dr. Arthur W. Benson, consultant pediatrician of the Child Health Service.

Saratoga County

The county society's committee on Medical Preparedness and Council of Defense, composed of Dr. W. H. Ordway, chairman, Dr. Carl R. Comstock, and Dr. Walter S. McClellan, have completed plans for protection of Saratoga County against any type of medical emergency it might encounter as a result of public disaster or war conditions, says a local newspaper.

County physicians have been classified according to their various specialties. From this survey a complete card index system has been evolved detailing all information concerning their activities and the zones selected for particular groups of medical men to cover in case of emergency.

Physicians in key localities are being selected to coordinate local efforts throughout the county and to dovetail with local defense councils.

Seneca County

At a meeting on December 11, Dr. Samuel Archer Munford, of Clifton Springs, talked on heart diseases and their treatments. Dr. Duane Walker was unable to be present and Dr. Baldwin presided. A discussion of group health and accident insurance for physicians was held and Mr. Lee, of Lodi, and Mr. Vaness, of Waterloo, expressed opinions on policies.

Suffolk County

In the current issue of the Suffolk County Medical Society *News Letter*, Dr. Frank Overton, Lt. Col., Inactive Reserve, U. S. Army, offers an article on "Preparedness for Defense in Suffolk County," in which he sets forth clearly the dangers to the people of Suffolk from raids by air and sea and the departments in the county that function for the protection of the people.

According to Dr. Overton, emergencies in times of peace or war are of two kinds: those affecting property and those affecting life and health. The recent countywide "blackout" was designed as a test of the efficiency of local means of dealing with both kinds of emergencies, especially those within the scope of the fire departments, hospitals, first-aid stations, and the medical profession.

Wayne County

A resolution unanimously requesting continuance of the Wayne County Health Camp was voted for presentation to the County Board of Supervisors by the county society at its annual meeting at Lyons in December.

Re-elected were the following officers: president, Dr. James L. Davis, Newark; first vice-president, Dr. George Pasco, Wolcott; second vice-president, Dr. Frank Wood, Lyons; secretary and treasurer, Dr. Thomas C. Hobbie, Sodus.

Herkimer County

Herkimer physicians have organized a disaster squad equipped to deal with any emergency.

With use of Steuben School granted by the Board of Education, the doctors met in December at the home of Dr. Floyd H. Moore, of Herkimer, local head of the Medical Preparedness Council, to arrange a permanent organization.

In order to make available a large number of nurses' aides, able to take over nontechnical duties from a comparatively small group of trained nurses, the doctors are cooperating with the Red Cross in teaching a regulation Red Cross nurses' aide course. Volunteering for this task were Drs. Frederick C. Devendorf, James W. Graves, Howard C. Murray, D. F. Aloisio, Albert L. Fagan, Byron G. Shults, James F. Gallo, Harold T. Golden, and Dr. Moore.

The county medical society has authorized purchase of a \$1,000 defense bond, its treasurer, Dr. Albert L. Fagan, has announced. The society, believed to be the oldest in the country, will buy the bond from funds already in its treasury.

Kings County

The pediatric section of the county society and the Academy of Medicine of Brooklyn will hold their January meeting on Monday, January 26, at 8:30 p.m. at the Kings County Medical Society, 1313 Bedford Avenue, Brooklyn. The following papers will be given: "Psychologic Problems of the Adolescent," by Dr. Harry Bakwin, of Manhattan; "Endocrine Problems of the Adolescent," by Dr. Jacob S. Beilly, of Brooklyn.—*H. S. Bikoff, M.D., Secretary.*

Livingston County

Dr. Kenneth T. Rowe, of Dansville, president of the county society, talked on "Common Problems of Urology" at a dinner meeting at Hotel LaDelfa in Mount Morris on December 10.

The first meeting, following organization of the Women's Auxiliary of the Livingston County Medical Society, also was held at Hotel LaDelfa, with Mrs. Kenneth Rowe, of Dansville, the president, in charge.

Montgomery County

At its annual meeting in December the county society voted to make certain payments to members who enter military service.

The schedule provides for paying single men \$75 per month; married men without children \$100 per month; and \$25 additional for each child under 18 years of age. The treasurer of the society is to assess and collect sufficient funds from the members of the group.

New York County

In cooperation with the Emergency Medical Service, the Medical Society of the County of New York and The New York Academy of Medicine have recently given a series of four lectures and demonstrations on advanced first aid.

At the first lecture Dr. George Baehr, director of the medical division of the National Office of Civilian Defense, spoke on the organization of emergency medical service. Captain Charles D. Scully, director of first-aid instruction for the New York Chapter of the American Red Cross, spoke on first-aid work.

The second lecture dealt with the emergency care and transportation of fractures, described by Dr. Robert H. Kennedy, chairman of the National Fracture Committee of the American College of Surgeons. Dr. Kennedy's lecture was followed by a movie on emergency splinting produced by the College's Regional Fracture Committee.

On January 5, Dr. Frederick W. Bancroft, president of the New York Surgical Society, presented the emergency care of abdominal injuries, head and chest injuries, and burns. On January 12, Dr. Lawrence M. Thompson, Chief of the First Aid Division of the American Red Cross, took up the emergency care of wounds, hemorrhage, and shock.

The seventh series of lectures for the public on the army, art and romance of medicine, sponsored by The New York Academy of Medicine, opened on November 13 with the delivery of the Linsly R. Williams Memorial Lecture by Dr. James Alexander Miller. His subject was "Tuberculosis: The Known and the Unknown." The second lecture was given by Dr. Tracy Jackson Putnam on "Mechanisms of the Mind." Other lectures in the series will be:

Dr. Abraham A. Brill, The Freudian Epoch (New York Academy of Medicine Anniversary Discourse), January 22.

Dr. Arnold L. Gesell, New Haven, Conn., Creative Behavior in Child and Adult, February 26.

Dr. Norman H. Jolliffe, History of Vitamin B, March 26
Dr. Anton J. Carlson, Chicago, Newer Knowledge on Nutrition, April 23.

The New York State Chapter of the American College of Chest Physicians will meet on January 23 in the Hotel Biltmore, New York City. The chairman of the morning session is Dr. Nelson W. Strohm, of Buffalo.

The program is as follows:

9:30—Registration of Members and Guests

9:45—"Tracheo-Bronchial Tuberculosis," by Dr. Louis H. Clerf, Professor and Director Department of Bronchoscopy, Jefferson Medical College and Hospital, Philadelphia, Pa.

Discussion opened by Dr. John Devereux Kernan, Professor and Director Department of Bronchoscopy, College of Physicians and Surgeons (Columbia University) and Presbyterian Hospital, New York City.

11:00—"Total Pneumonectomy," by Dr. Julian Johnson, Director Department of Thoracic Surgery, University Pennsylvania Hospital, Philadelphia, Pa.

Discussion opened by Dr. Samuel Olcott Thompson, Associate Professor Surgery, New York Medical College, and Director Department of Thoracic Surgery, Metropolitan Hospital, New York City.

1:00—Lunch

Guest Speaker—Dr. Samuel J. Koletzky, New York City, Medical Director, Selective Service Administration for the State of New York; President of the Medical Society of the State of New York. Subject: "Medical Preparedness."

Hospital News

Emergency Nursing Service

THE formation of a master plan for a 24-hour emergency nursing service for New York City, covering the 30 Health Districts and involving more than 38,000 registered professional nurses, was announced on December 11 through the local Office of Civilian Defense. The plan will be put into operation by Dr. E. M. Bernecker, Chief of the Emergency Medical Service for the City of New York, through whose office at 125 Worth Street, New York, all disaster calls involving nursing service will clear.

At the request of the Emergency Medical Service, a nursing council, representative of the professional nursing organizations and the community's nursing services—including institutional, public health and private duty—is setting up the plan by which all known nurses will be assigned to specific health districts. A call system is being devised to reach each nurse through a designated hospital or other local headquarters.

The nurses themselves are being asked to stand by until full instructions reach them through the organizations with which they are affiliated. Such instructions will include the place to report, a description of suitable uniforms and identifications, and all other pertinent information.

Newsy Notes

ON December 15 seventy-two hospitals in Greater New York (thirty-five in Manhattan) had completed the establishing of emergency field units as outlined in the Medical Division *Bulletins Nos. 1 and 2* from the Office of Civilian Defense.

With the end of 1941 came the close of the United Hospital Fund carried on for the past several weeks in New York City and vicinity. As of December 13, there had been collected \$1,032,214.04, and the goal set was \$1,784,000. The number of subscribers, as well as the amount collected, was greater as of this date than in 1940. Seventy-five volunteer nonprofit hospitals benefit by the fund.

"If a hospital is great in spirit, original in its outlook, creative in its service and inspiring in its community relationships, that hospital will assume a definite personality, for the success of an institution is not measured by its size alone," said Mr. Raymond P. Sloan, associate editor of *Modern Hospital*, at a recent dinner meeting of the board of trustees and medical board of the Staten Island Hospital.

"In this country we are studying more closely hospital service in its relationship to community health needs. . . .

"What we need more today than anything else is faith with which to fight, faith in the fact

that service to suffering humanity will bring its own reward. With such faith we will look into the future fearlessly, and plan for that future, with the careful consideration of the role that each has to play. We will build our hospitals, our doctors' workshops on a solid foundation, designing them to the pattern of the community's health needs."

"Teamwork between hospital trustees and the medical staff is essential if our voluntary hospitals are going to uphold their tradition of service to the suffering and to function as modern medical and educational centers," he said.

Dr. Frank F. Tallman has been appointed director of the Study of Parole and Family Care by the Temporary Commission on State Hospital Problems, of which Homer Folks, S.C.A.A. secretary, is chairman.

Through the courtesy of the State Department of Mental Hygiene, Dr. Tallman was given a leave of absence in August from his duties as clinical director of the Rockland State Hospital, in order to give full time to the study.

Appointment of the first woman physician to the staff of Herkimer Memorial Hospital was made recently when the directors approved the application of Dr. Margarete Kotrnetz, 133 North Main Street, formerly of Vienna, who started practice here recently.

On November 27 the *Brooklyn Eagle* carried an article on the use of music in hospitals. Mrs. Harriet A. Seymour of 82-16 Beverly Road, Kew Gardens, Long Island, is the founder of the National Foundation of Musical Therapy, which has its headquarters in Steinway Hall, New York City. Since October, Mrs. Seymour has been conducting training classes there. Those entering this field need not be concert quality musicians. A sympathetic personality and a desire to help suffering people are requisites, however.

Certain types of music have been found most effective in dealing with certain types of cases. For example, one type of music is used for shell shock or depressed patients, another type for tubercular patients, and another type for those suffering pain. Doctors hail musical therapy as an adjunct to their treatment.

Improvements

The cornerstone of the Buckley Pavilion of the Methodist Hospital, a nine-story structure now under construction at Sixth Street near Seventh Avenue, was laid on December 4 by Bishop Francis J. McConnel, bishop of the New York area of the Methodist Church. Hersey Egginton, president of the institution, presided at the ceremonies and was assisted by Dr. Chester C. Marshall, director of the hospital.

Dr. Ralph Sheldon, Lyons, was named as delegate to the State Medical Association convention, with Dr. S. W. Houston, Wolcott, alternate.

Dr. D. F. Johnson, Newark, was elected to the

board of censors to replace Dr. Myron E. Carmer, Lyons. Other members of the board are Dr. George S. Allen, Clyde, and Dr. Arthur Besemer, Marion.

Deaths of New York State Physicians

Name	Age	Medical School	Date of Death	Residence

DOCTORS ARE HUMAN BEINGS

"Physicians are dying needlessly every year of advanced disease. . . many have never had a physical examination since they were examined for life insurance. . . it is a real tragedy to find hopeless advanced cancer in a physician." These calamitous lines appear in a *Bulletin* for the American Society for the Control of Cancer.

In contrast, one reads in the September issue of the Metropolitan Life Insurance *Bulletin*: "New Army in Excellent Health," "Average Length of Life Increased by One-Third Since 1900," and "Health of American Wage-Earners Remains at High Level"—but at what level is the health of the American doctor?

Perhaps patriotism will at last accomplish what family admonitions and mere possession of knowledge have failed to do, for a doctor's health is no longer a personal matter but one of vital public concern. To maintain the health of the nation—"our first line of defense"—is not an easy task under any conditions but it is now made doubly hard by the acute shortage of physicians due to so many having been called into military service. We can no longer break the rules. *It is time to take our own medicine.*

THE GIRL WHO WORKS FOR A DOCTOR

. . . enters upon a real career and, it seems to me, one of the most useful careers that is possible for her to fulfill," says Miss Marjorie Euler in "Highlights of Twenty-Five Years of Service," published in the *Journal of the Michigan State Medical Society* for September. The article is so complete that it can easily serve as a handbook for the doctor's secretary. The author even counsels on such ticklish problems as explaining away your being late for an appointment when she knows you are lunching with your best crony telling about the big one that got away! She goes into: office housekeeping and ethics; the variety of patient personalities; instrument and book salesmen; telephone calls (with phonetic tips); the insurance patient; and the all-important subject of bills and mail collections (even to sample letters).

On personal appearance, she says: "Be as attractive as possible but this doesn't mean brilliantly colored claws for nails." And on the subject of promptness: "Whatever time your office opens, be at least five minutes ahead of time." In other words: "Be the best 'Girl Friday' you can."

Medical Preparedness

Complete Plans for Handling Professional Personnel in War

Function of Procurement and Assignment Service and Names of Committeemen for Corps Areas Are Announced

AN OUTLINE of the organization of the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians and the names of the corps area committeemen representing the three professions are announced in the Medical Preparedness Section of the *Journal of the American Medical Association* for December 27. The announcement says:

"At a meeting in Chicago of the board of the Procurement and Assignment Service with the Committees on Medical Preparedness of the American Medical Association, the American Dental Association, and the American Veterinary Medical Association, a definite organization was completed for the functioning of this service in relationship to needs of professional personnel in the war."

Physical Requirements for Physicians in Service

"The Procurement and Assignment Service will make available shortly through publication in the periodicals of the professions concerned a tabulation of the physical requirements for physicians applying to any of the federal services."

Evaluation of Physicians Through County Medical Societies

"More than two thousand county medical societies have already made available ratings of physicians available in such counties as regards their employment in essential services and their availability for the Army and Navy Medical services. Steps will be taken to speed up the completion of similar evaluations in the remaining counties."

Questionnaire

"Approval was given to the immediate publication in the professional periodicals of a questionnaire addressed to all members of the medical profession urging them to enroll at once with the Procurement and Assignment Service so as to make available immediately a pool of physicians from whom applicants for commissions might be drawn promptly. The immediate needs of the Army are for men in the grades of lieutenant and captain—that is to say, men particularly under the age of 45."

The National Roster

"A conference was held with representatives of the National Roster, which is a subsidiary of the National Resources Planning Board. Arrangements were made for joint action with the Budget Committee in Washington to secure the necessary funds for operation of the National Roster covering the medical profession and for the regional office in the headquarters of the American Medical Association."

Corps Areas

"Dr. James A. Paullin [Atlanta, Ga.] described the methods by which evaluation has been made of all men in the Fourth Corps Area and also the method by which ratings have been given to specialists

"Approval was given to the constitution of committees in each of the corps areas and associated naval districts to function as advisory to the corps area commander, the committee to consist of a chairman who will be the corps area representative of the Committee on Medical Preparedness of the American Medical Association, *one physician representing medical education, one representing the hospital organizations, two physicians selected at large, two dentists and one representative of the veterinary profession.* The chairmen nominated for the various corps areas are as follows:

First—DR W G PHIPPE, Salem, Massachusetts
Second—DR A W BOOTH, Elmira, New York
Third—DR A M SHIPLEY, Baltimore
Fourth—DR EDGAR GREENE, Atlanta, Georgia
Fifth—DR E L HENDERSON, Louisville, Kentucky
Sixth—DR CHARLES H PHIFER, Chicago
Seventh—DR ROY W FOUTS, Omaha
Eighth—DR SAM E THOMPSON, Kertville, Texas
Ninth—DR CHARLES A DUKES, Oakland, California

"Other physicians nominated to these corps area boards include:

First—DR DEERING G SMITH, Nashua, New Hampshire, DR LUCIUS KINGMAN, Providence, Rhode Island
Second—DR S J KOPETZKY, New York City, DR W J CARRINGTON, Atlantic City, New Jersey
Third—DR C H HENNINGER, Pittsburgh, DR HUGH H TROUT, Roanoke, Virginia
Fourth—DR ALFRED A WALKER, Birmingham, Alabama, DR EDWARD H JELKS, Jacksonville, Florida
Fifth—DR ROBERT COVARD, Wilmington, Ohio, DR LARUE CARTER, Indianapolis
Sixth—DR J MILTON ROBB, Detroit, DR STEPHEN E GAVIN, Fond du Lac, Wisconsin
Seventh—DR F L LOVELAND, Topeka, Kansas, DR ROBERT L PARKER, Des Moines, Iowa
Eighth—DR HOLMAN TAYLOR, Fort Worth, Texas, DR JOHN W AMESSE, Denver
Ninth—DR JOHN FITZGIBBON, Portland, Oregon, DR JOHN H O SHEA, Spokane, Washington

"A regional office is to be established in each corps area for the maintenance of information, for supervision of the state committees and to act as a consulting body on all matters relating to the functions of the Procurement and Assignment Service in the corps area. The following dentists were recommended for appointment:

First—DR PHILIP ADAMS, Boston, DR FRANK W ROUNDS, Boston
Second—DR WILLIAM McG BURNS, Brooklyn, DR ALLAN T NEWMAN, New York City
Third—DR LUCIAN BRUN, Baltimore, DR HARRY BEAR, Richmond, Virginia
Fourth—DR CLAUDE R WOOD, Knoxville, Tenn., DR RALPH R BYRNES, Atlanta, Georgia
Fifth—DR EARL LOWERY, Columbus, Ohio, DR WENDELL POSTLE, Columbus, Ohio
Sixth—DR LEO KREMER, Chicago, DR PAUL H JESERICHT, Ann Arbor, Michigan

The new wing to the Herkimer Memorial Hospital was expected to be ready for occupancy by January 1, 1942.

. . .

The Mercy Hospital in Watertown, conducted by the Sisters of Mercy, has been granted a \$100,000 federal allotment for improvements including construction of a nurses' residence under a defense public works project approved recently by President Roosevelt. The entire program is to cost an estimated \$400,000 of which \$300,000 will be supplied by the hospital.

. . .

Syracuse General Hospital will be able, according to present progress, to make a contribution of 30 to 40 additional beds to relieve the existing shortage by February, providing weather is favorable.

One of the smaller units in the expansion plan for which the public contributed \$500,000 is far enough along to indicate completion and occupancy sometime in the second month of the year.

. . .

A gymnasium incorporating the most up-to-date features is being completed at Brooklyn State Hospital, where it will provide recreational facilities for the 3,450 mental patients, as well as doctors and attendants.

Constructed at a cost of \$150,000, it is described by Dr. Clarence H. Bellinger, medical superintendent, as the finest hospital gym in the state. The main gym floor, marked as a full-size basketball court, is being equipped with apparatus for physical training purposes. In the basement are four bowling alleys and a separate room is being outfitted with pool and billiard tables.

By means of a mile-long tunnel connecting buildings of Kings County Hospital with affiliated pavilions and institutes, the gymnasium will be accessible from all buildings.

In a move to facilitate research among the incurably sick, the Jewish Sanitarium and Hospital for Chronic Diseases in Brooklyn has created a special division among its medical staff to begin intensive investigations for treatment of active chronic cases, Abraham S. Singer, president of the institution, has announced.

. . .

Archbishop Spellman and other prominent members of the Catholic clergy participated recently in ceremonies dedicating the opening of a new nurses' wing and other improvements at St. Elizabeth's Hospital at 190th Street and Fort Washington Avenue.

. . .

The new x-ray installation recently completed in Oneida City Hospital at a cost of approximately \$13,000 is the latest and most modern of its kind in that part of the country.

. . .

In order to provide means for unhurried escape for the children at Neponsit Beach Hospital, new safety stairs will be built that will allow the crippled children to reach safety quickly in case of fire at the big West End institution. This is the latest development in the complete modernization of the hospital that has been under way by the WPA under the sponsorship of the Department of Hospitals. The announcement of the improvement was made by Major Irving Huie, WPA administrator for New York City.

. . .

The new Faxton Hospital in Utica under construction for the past eighteen months, was formally dedicated on December 7.

The dedication ceremonies marked the completion of the project which has involved the expenditure of approximately \$200,000.

NEW YORK HEART ASSOCIATION TO MEET

A joint scientific session of the New York Heart Association and the Medicine Section of The New York Academy of Medicine will be held on Tuesday, January 20, at the Academy, 2 East 103rd Street, New York City. The session, starting at 8:45 p.m., will be preceded by the annual dinner meeting of the association's council at 7:00 p.m. The Heart Association is a division of the New York Tuberculosis and Health Association.

The session program is as follows:

1. Report of the New York Heart Association by Dr. Ernst P. Boas, chairman.

2. "Experimental and Clinical Studies in the Use of Anti-Coagulants in Cardiovascular Dis-

ease, with Special Reference to Heparin and Dicoumarin," by Dr. Andrew G. Prandoni, Department of Internal Medicine, New York Post-Graduate Medical School and Hospital, Columbia University. Discussion by Dr. Irving S. Wright, professor of medicine, New York Post-Graduate Medical School and Hospital, Columbia University.

3. "Some Chemical Changes in the Myocardium Accompanying Heart Failure," by Dr. Victor C. Myers, professor of biochemistry, Western Reserve University, Cleveland. Discussion by Dr. Maurice Bruger, Department of Medicine, New York Post-Graduate Medical School and Hospital, Columbia University.

Woman's Auxiliary

To the Medical Society of the State of New York

GREETINGS, Folks. It's your convention chairman turning in with an invitation and a bit of news on the forthcoming convention.

Kings, Queens, Nassau, Suffolk, Rockland, and Orange counties extend to all doctors' wives, whether members of an auxiliary or not, a most cordial invitation to register at our headquarters, Waldorf-Astoria Hotel, and attend all the meetings and social functions of the Medical Society of the State of New York which is scheduled for April 27, 28, 29, 30, 1942.

The Medical Society of the State of New York graciously and generously assigned us the grand Starlight Roof. The Convention Committee women are laying an excellent foundation, and we ask that all doctors' wives help us in the building of the structure of the forthcoming convention.

That's all—until the next JOURNAL and more news.

Signing off,

MABEL A. PORLMANN
Convention Chairman

County News

Albany. A luncheon was held at the De Witt Clinton Hotel, on December 9, Mrs. George B. Adams, state president, was the guest speaker. Columbia, Rensselaer, and Schenectady counties were well represented.

Madison. Congratulations to Mrs. L. S. Preston, of Oneida, newly elected president, and Mrs. A. J. Zaia, of Oneida, who has been appointed press and publicity chairman.

Nassau. At the November meeting Dr. Le Grand Kerr, of Brooklyn, spoke on "Dames, Doctors and Doings in the Drab Nineties." The talk was most interesting, humorous, and enlightening. He mentioned changes in the laymen's attitude with regard to hospitals, fresh air in aiding proper care of the sick and, last but not least, the change in women's attitude toward clothing—from corsets to freedom. Guests at this meeting were Mrs. Le Grand Kerr, Dr. B. D. St. John, and Dr. Louis Van Kleeck of the Nassau County Medical Society. Hostess for the evening refreshment hour was Mrs. Louis Lally.

At the annual Christmas party the members brought toys for children (ages from 12 through 16) who are in foster homes. The next meeting will be on January 27 at the Nassau Hospital Auditorium at 8:45 p.m. Moving pictures will be shown by Dr. Eugene H. Coon.

Onondaga. A formal dinner was held on December 21 in the small ballroom of the Hotel Syracuse. Covers were laid for 130 members. Mrs. John Buettner and Mrs. Francis R. Irving were chairmen of the evening. Mrs. George Murdock was in charge of program and Mrs. John Hogan was in charge of tickets. Mrs. Winthrop Pennock, past-president and present director of Woman's Civilian Defense Work in New York State, gave a sincere appeal for volunteer workers and cooperation in organizing the com-

munity defense. Seated with Mrs. Pennock at the speakers' table were Mrs. Edgar M. Neptune, Mrs. Brooks McCuen, Mrs. Walden Retan, Mrs. John Buettner, Mrs. Ambrose T. Lawless, Mrs. Leo Gibson, and Mrs. Francis Irving. Accordion players entertained during the dinner hour. Mrs. Marcus Richards, of Tully, gave a few clever readings, and Mrs. Russell Harder entertained during the evening.

Rensselaer. Two new members were admitted, Mrs. Irving Strosberg and Mrs. James J. Dunne; Mrs. Fred W. Lowinger, of Albany, was a guest at the meeting. Tea was served by Mrs. Minnie B. Stannard, chairman of the hospitality. She was assisted by Mrs. Richard P. Doody, Mrs. John B. Carroll, Mrs. Arthur W. Benson, and Mrs. John Enzien. Mrs. A. J. Hambrook and Mrs. Charles E. Bessey presided at the tea table.

At the annual Christmas party officers were elected for the ensuing year.

Rockland. The November meeting was held at the home of Mrs. F. Schwartz, of Spring Valley. There were fourteen members present. Mrs. T. Olmstead, president, presided. The committees for the year were appointed. Mrs. S. Kwalwasser—*Hygeia*, Mrs. A. Schechner—publicity and press, Mrs. I. Deutsch—legislation, Mrs. A. Magid—program, Mrs. K. Blatt—printing and supplies. Rockland County is to be one of the hostesses to the counties at the State Convention at the Waldorf in April. Mrs. Schwartz and Mrs. Selman, of Spring Valley, Mrs. Rooney and Mrs. Schechner, of Nyack, Miss Hirsch, of Haverstraw, and Mrs. Olmstead, of Pearl River, volunteered to work on committees at the convention. The auxiliary is still working on its project to get contributions for Bundles for Britain. The next meeting will be held at Nyack at the home of Mrs. A. Schechner on January 20.

Saratoga. Mrs. James F. Roohan was elected president of the auxiliary. The meeting was held at the Nurses Lounge, with Miss Adeline M. Hughes, superintendent of the hospital, acting as hostess for the evening. Mrs. Robert E. Rockwell was elected vice-president; Mrs. Edward J. Callahan, Schuylerville, secretary; and Mrs. Harry L. Loop, treasurer. Annual reports showed a year of activity and progress in all committee projects. Mrs. Thomas E. Bullard, Schuylerville, who retired as president, was presented with a past officer's pin and with an evening bag as a token of her leadership and work. Mrs. Leon Chadwick of the Homestead Sanatorium gave a Christmas reading. There was a Christmas tree and gifts were distributed. New members welcomed were Mrs. Richard D. Bullard and Mrs. William Van Dorn, of Mechanicville, and Mrs. Fred J. Pratt and Mrs. Carl J. Thompson, of Mount McGregor. Miss Hughes was assisted by the following hostesses: Mrs. Joseph Lebowich, Mrs. Thomas J. Goodfellow, Mrs. Rockwell, Mrs. Richard Y. Lindsay,

Seventh—Dr. F. A. PIERSON, Omaha; Dr. A. W. BRYAN, Iowa City.

Eighth—Dr. H. G. DUCKWORTH, San Antonio, Texas; Dr. FRED C. ELLIOTT, Houston, Texas.

Ninth—Dr. B. C. KINGSBURY, San Francisco; Dr. E. G. SLOMAN, San Francisco.

"The following veterinarians were recommended for appointment:

First—Dr. R. W. SMITH, Concord, New Hampshire.

Second—Dr. R. R. BIRCH, Ithaca, New York.

Third—Dr. MARK WELSH, College Park, Maryland.

Fourth—Dr. B. T. SIMMS, Auburn, Alabama.

Fifth—Dr. A. F. SCHALK, Columbus, Ohio.

Sixth—Dr. WARD GILTNER, East Lansing, Michigan.

Seventh—Dr. H. D. BERGMAN, Ames, Iowa.

Eighth—Dr. M. B. STARNES, Dallas, Texas.

Ninth—Dr. C. M. HARINO, Berkeley, California.

"The names of the physicians representing medical education and those of the hospital organizations will be published later.

"The technic was also described for supplying the names of physicians to appropriate governmental agencies according to the present methods of functioning of the Procurement and Assignment Service."

Trained Attendants to Replace Interns on Ambulances

DR. WILLARD C. RAPPEYE, Commissioner of Hospitals, New York City, announced on December 21 that it probably would be necessary in the near future to discontinue interns on the ambulances of both the voluntary and municipal hospitals, due to the increasing shortage of interns in the hospitals of the city. Because of the need of medical officers for the expanding Army and Navy, many interns will be called to military duty.

Under the plan now contemplated, trained attendants competent to deal with first aid and emergency care will be provided on each ambulance. All patients requiring diagnosis or medical attention will be promptly brought to the hospital, where they will be seen in the emergency ward and where proper diagnosis and treatment will be established. Those who require hospitalization will be admitted; those who require only temporary care will be kept in the emergency ward until they can be discharged.

Dr. Rappeye stated that the Department of Hospitals and the voluntary institutions have for some months been working on plans to provide trained ambulance attendants to take the place

of interns on the ambulances. In practically all large cities the ambulance service is manned by nonmedical personnel. Commissioner Rappeye pointed out that at the present time less than half of the ambulance calls are for emergencies, which is the real purpose of ambulance service. He said that many of the calls were for medical attention in the home or for minor injuries which could be taken care of in some outpatient department or by a neighborhood physician. It is highly important that the ambulance services of the city under present circumstances be reserved for real emergencies. Commissioner Rappeye appeals to individuals, families, and community organization to cooperate by going to private physicians or to outpatient departments and hospitals for medical attention rather than calling ambulances to their homes for ordinary illnesses or minor complaints.

Dr. Rappeye emphasized that the program now being studied would not in any way change the medical and nursing personnel in the eighty emergency units now organized throughout the city that are standing by for any major catastrophe in the community.

A.M.A. BROADCASTS

Doctors at Work, the dramatized radio program broadcast by the American Medical Association and the National Broadcasting Company, is on the air for its second season: from 5:30 to 6 P.M. eastern standard time on Saturday evenings.

Doctors at Work, a successful serialized story broadcast last year, dealt with the experiences of a fictitious but typical American boy choosing medicine for his vocation and proceeding to acquire the necessary education and hospital training for the private practice of medicine. Interwoven with the personal story of young Dr. Tom Riggs and his fiancée, Alice Adams, was the romance of modern medicine and how it benefits the doctor's patients. The new series of broadcasts is taking up where last year's story left off—namely, with the marriage of Tom Riggs and Alice Adams—and depicts the subsequent life of a young doctor and his wife in time of national emergency in a typical medium-sized American city.

MUTINY ON THE BOUNTY

Buried beneath a mass of dry statistics, we noticed a report recently that our large "Foundations" are now devoting a third of their money-grants to medical research, medical teaching, and other facets of the healing art. The same study also reveals that education, for decades the pet project of the "Foundations," has been ousted from the number one position by medicine, which is now their prime beneficiary. This solicitude is matched only by increasing government concern with medical care, and our profession is thus the victim of an embarrassment of riches.

Now this is all flattering and, at first glance, comforting. Second thought, however, reveals a faint cloud in the horizon. It seems that the man who pays the piper is still entitled to call the tune on any request program. Can it be that the philanthropists and politicians who are opening the purse are also anxious to dictate the policies? Or is this petulant query just another Mutiny on the Bounty? —*J. Med. Soc. N. J.*

Wyeth's **ELIXIR** **B-PLEX**

REG. U. S. PAT. OFF.

THE NATURAL VITAMIN B-COMPLEX

Current medical opinion states that most vitamin B deficiencies are multiple and therefore it is essential to treat such deficiencies with the complete vitamin B complex rather than with just the known synthesized B vitamins.

ELIXIR B-PLEX is a palatable elixir of yeast concentrate. It is a natural source of the water-soluble active constituents of a potent brewer's yeast containing the unidentified fractions as well as the known factors of B complex.

Write "ELIXIR B-PLEX, Wyeth" for your B avitaminosis cases.

Supplied in eight-ounce bottles.

JOHN WYETH & BROTHER, INC., PHILADELPHIA, PA.
Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

Miss Addie E. Farwell, Mrs. G. Scott Towne, and Mrs. Webster M. Moriarta.

Schenectady. The November meeting was held at Glenridge Sanitarium. Mrs. Eleanor Nash, of New York, fashion expert, gave a talk on the latest styles and the fashions of today and the coming year. She was introduced by Mrs. Charles F. Rourke, program chairman. Mrs. E. MacDonald Stanton presided at the meeting. The annual Christmas tea was held at the home of Mrs. Albert Grussner, with Mrs. James M. Blake as hostess. Mrs. A. S. Fay presided at the tea table, assisted by Mrs. George A. Reich and Mrs. George Von Borstel.

Warren. The December meeting was held at the home of Mrs. John Griffin. Mrs. Hulsebach presided, and twenty-two members were present. The members decided to sponsor a first-aid class beginning January 5, at the Red Cross Headquarters. Sixteen members signed up for the course. Tea was served following the meeting; Mrs. Lefevre and Mrs. Thayer poured. Hostesses assisting Mrs. Canaday were Mrs. Sheldon, Mrs. Davis, Mrs. Mitchell, and Mrs. Haukins. Mrs. Wilmer, wife of the Hospital Superintendent, was a guest at the tea.

Washington. Fourteen members and four guests were present at the November meeting. Mrs. Irwin V. Decker, president, presided. Mrs. Decker thanked all officers and chairmen for their fine cooperation during her year of office. Reports of all chairmen of committees were read. The following officers were elected: Mrs. Kennedy Creevey, Cambridge, president; Mrs. Irwin V. Decker, Salem, vice-president; Mrs. Clayton Oestreicher, Sushan, secretary; Mrs. R. E. Borrowman, Fort Edward, treasurer. The auxiliary dues were changed from \$2.00 to \$1.50. Mrs. Edward B. Mates was welcomed as a new member. The auxiliary has assisted with the sale of Tuberculosis Seals. Crimson berries in a silver bowl and white candles in silver holders graced the tea table. Mrs. Robert McClellan and Mrs. Denver presided.

We do not know what the year ahead will bring. During December, 1941, declarations of war on Japan, Germany, and Italy have come. We are in total war. We must face it and serve as never before. With a prayer for "Peace on earth, good will to men," your publicity chairman sends each member a New Year's Greeting.

DEPRESSIVE STATES IN THE SOLDIER

In an article in the *British Medical Journal*, R. F. Tredgold recommends rest, general psychotherapy, and prolonged narcosis for depressive states in the soldier.

"...The patients were kept in bed for at least twenty-four hours, practically all for forty-eight hours, and some for a week. During this time the question of future treatment and of narcosis therapy was considered. The majority of the patients, however, were those whose progress appeared satisfactory; they were gotten up and given light jobs, usually in the ward, requiring little concentration, responsibility, or perseverance. Their existence was ruled by a fairly strict routine time table; it regularly included fresh air and adequate meals.

"Gradually their occupation was made more interesting and more vigorous, and so far as possible in tune with their own hobbies or occupations. This was not always feasible, and rug and basket making, digging, and weaving proved valuable substitutes, with the help of varied physical training and entertainment such as cinemas and organized games.

"General psychotherapy consisted in giving individual encouragement and reassurance and, later, included a series of talks, leading the patient to adjust his personality to cope with his difficulties so far as was possible and stressing the fact that he had passed through an illness caused, like any other, by physical factors.

"Those patients whose progress appeared unsatisfactory after a few days' observation or who suffered acute anxiety were recommended prolonged narcosis."—Abstracted in *Archives of Physical Therapy*

THE "TALKING MIRROR"

Reactions observed among large groups of persons who saw the State Health Department's new exhibit on cancer, which was displayed for the first time at the Erie County Fair in Hamburg, indicate that the subject is of interest to persons in all walks of life and of all ages.

The central feature of the exhibit is the "talking mirror." Twelve questions on cancer control are posted and when the spectator inserts a plug into a numbered hole corresponding to the number of a question on the panel board in front of the mirror, the question is answered, apparently by the mirror.

The operator concealed behind the mirror, first explains that the voice is not reproduced by mechanical means and then proceeds with the answer. During the narration, the front lights are dimmed and rear floodlights are turned on so that the mirror becomes transparent and the operator is seen. In this way many instructive facts about cancer are given, audience interest being held by the change of light on the mirror and the spectator's operation of the apparatus.

During the display of the exhibit the demand was so great for repeat performances that it was necessary to employ three attendants so that it might be in operation from early morning until late in the evening.

The "talking mirror" together with operating personnel is available only to large conventions and meetings of statewide organizations. Requests should be addressed to the Bureau of Visual Instruction, New York State Department of Health, Albany, New York.—*Health News*

Neither Sagebrush nor Marsh Grass

Sagebrush grows best in a desert, and marsh grass blooms in a swamp. The human colon seeks a middle course between these two extremes.

Thus the normal stool characteristic of normal function is neither hard-packed and dehydrated as found in constipation—nor almost fluid as found in diarrhea.

In the corrective treatment of constipation, the success of

MUCILOSE

lies in its capacity to produce a nearly normal condition of the fecal content by controlling "water-balance."

In a recent investigation the increase in hydration produced by Mucilose was found to be nearly double that of tragacanth preparations.*

No Lack in Biolac!

WITH THE sole exception of vitamin C, Biolac provides completely for the formula needs of normal infants throughout the entire bottle period. From the time when infants consume a full quart of formula per day, here's how certain essential food factors supplied by Biolac feedings compare with the minimal nutritional requirements recognized by the U. S. Food and Drug Administration.

	MINIMAL REQUIREMENTS	BIOLAC FEEDINGS
PROTEIN (gms./lb. body weight) . . .	1.4 to 1.8* . . .	2.2†
CALCIUM (gms./day)	1.0*	1.0
IRON (mgms./100 calories)	0.75	1.25
VITAMIN A (U.S.P. Units/day)	1500.	2500.
VITAMIN B ₁ (U.S.P. Units/day)	83.	85.
VITAMIN B ₂ (mgms./day)	0.5	2.
VITAMIN D (U.S.P. Units 100 calories)	50.	63.

*The Food & Drug Administration has not promulgated minimum requirements for protein and calcium in infancy. The values shown are those recommended by the National Nutrition Conference

†When Biolac formulae are fed in the amount of 2½ fl. oz./lb. body weight.

Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrate of vitamins A and D from cod liver oil, and ferric citrate. Evaporated, homogenized, sterilized

REVIEWED

Chemistry of Food and Nutrition. By Henry C. Sherman, Ph.D. Sixth edition. Octavo of 611 pages. New York, Macmillan Company, 1941. Cloth, \$3.50.

This is a new edition of the best work on its subject. Although originally prepared as a college text, this book should be of great service to those who are interested in "the kinds and amounts of elements and other foodstuffs that are needed in our nutrition, the considerations which should underlie our judgments of food values, and the choice and use of foods for the nutritional improvement of life."

Recent advances in nutrition have been many and varied. Consequently, every chapter in the volume has been revised. The half of the book devoted to vitamins has been completely rewritten. Those who have not been keeping up to date on all the newest work in this field will find it worth their while to study this volume.

It need not be necessary to add that Dr. Sherman's eminent position in the field of food and nutrition chemistry guarantees the dependability and accuracy of all the contents.

ETHEL PLOTZ BERMAN

Collected Papers of the Mayo Clinic and the Mayo Foundation. Edited by Richard M. Hewitt, M.D., A. B. Nevling, M.D., Harry L. Day, M.D., and others. Volume XXXII. Octavo of 1,190 pages, illustrated. Philadelphia, W. B. Saunders Company, 1941. Cloth, \$11.50.

The general plan of the annual Mayo Clinic volume is deservedly well known. Most of the important contributions made by the members of the staff to the current literature are included either in full or in part, depending on the length of the article and its interest. There are numerous articles that illuminate every branch of medicine, and nearly every advance made during the year is more than adequately covered.

A novel feature of this year's collection is the section on Military Medicine. There are 180 pages of material that will prove of interest to

all physicians. Among the articles are those on march foot, shock, transfusions of plasma, traumatic surgery, high altitude, skin grafting, etc. In short, this section, as well as the entire volume, will appeal to all practitioners in every field.

MILTON PLOTZ

Synopsis of Diseases of the Heart and Arteries. By George R. Herrmann, M.D. Second edition. Duodecimo of 468 pages, illustrated. St. Louis, C. V. Mosby Company, 1941. Cloth, \$5.00.

The author has completely revised the second edition of this excellent book. In a short space it is quite surprising how much information is included. It is inevitable, during condensation, that some of the explanations are rather meager and would be a little hard to comprehend by those not already well familiar with the literature. This particularly applies to some of the theoretic discussions and to parts of the section on electrocardiography. However, this can readily be overcome if desired by referring to treatises that discuss these phases in more detail. Anyone who knows the contents of this book thoroughly is familiar with the most modern conceptions of cardiology. The book can be recommended with confidence for those who desire a short summary of diseases of the heart and arteries.

J. HAMILTON CRAWFORD

Trauma and Disease. Edited by Leopold Brabdy, M.D., and Samuel Kahn, M.D. Second edition. Octavo of 655 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$7.50.

With the increase of compensation laws and the growth of industrial medicine, a practical book showing the effects of a single trauma in producing disease is timely, for it covers nearly every phase of medicine including gynecology and obstetrics and also trauma of the nervous system and mental disorders which may ensue.

One must realize, however, that the contents

[Continued on page 184]

No Lack in Biolac!

WITH THE sole exception of vitamin C, Biolac provides completely for the formula needs of normal infants throughout the entire bottle period. From the time when infants consume a full quart of formula per day, here's how certain essential food factors supplied by Biolac feedings compare with the minimal nutritional requirements recognized by the U. S. Food and Drug Administration.

	MINIMAL REQUIREMENTS	BIOLAC FEEDINGS
PROTEIN (gms./lb. body weight) . . .	1.4 to 1.8* . . .	2.2†
CALCIUM (gms./day)	1.0* . . .	1.0
IRON (mgms./100 calories)	0.75 . . .	1.25
VITAMIN A (U.S.P. Units/day)	1500. . . .	2500.
VITAMIN B ₁ (U.S.P. Units/day)	83. . . .	85.
VITAMIN B ₂ (mgms./day)	0.5 . . .	2.
VITAMIN D (U.S.P. Units 100 calories) .	50. . . .	63.

*The Food & Drug Administration has not promulgated minimum requirements for protein and calcium in infancy. The values shown are those recommended by the National Nutrition Conference.

†When Biolac formulas are fed in the amount of 2½ fl. oz./lb. body weight.

Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrate of vitamins A and D from cod liver oil, and ferric citrate. Evaporated, homogenized, *sterilized*.

Borden's BIOLAC

A BORDEN PRESCRIPTION PRODUCT

[Continued from page 182]

in this edition are much curtailed because the book is not large enough to cover so vast a subject. The extensive bibliography at the end of each chapter gives an opportunity to look up further information. It is recommended to all those who are engaged in compensation work.

MAURICE J. DATTELBAUM

Orbital Tumors. Results Following the Transcranial Operative Attack. By Walter E. Dandy. Octavo of 168 pages, illustrated. New York, Oskar Piest, 1941. Cloth, \$5.00.

This excellent profusely illustrated monograph serves strongly to emphasize the role of the neurosurgeon in the surgical treatment of orbital neoplasms. The advantages of the transcranial approach versus the conventional modes of attack, as carried out by the ophthalmologic surgeon, will become immediately obvious when one notes the high incidence of intracranial extensions.

The book is written in the case-history manner and combines a wide variety of both benign and malignant lesions, including osteomas, fibromas, meningiomas, secondary carcinomas and sarcomas, and a few well-described cases of Schüller-Christian's disease.

Of particular interest to the ophthalmic surgeon, the neurologist, and the neurosurgeon, the book offers a sufficient variety of pathologic entities to be of more than passing interest to the general practitioner at large.

RICHARD GRIMES

Essentials of Endocrinology. By Arthur Grollman, M.D. Octavo of 480 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1941. Cloth, \$6.00.

This is a well-written account of what the author considers the essentials of endocrinology. As a pharmacologist, he is at his best discussing the pharmacologic highlights of the subject, and it is understandable that this phase has received relatively more attention than the pathologic and clinical aspects.

On the clinical side, it must be regretfully stated that the volume is disappointing. References are to the literature, and there is not present in the text the emphasis of personal experience. This tends to becloud diagnosis and therapy and lessens the value of the book as a guide in endocrinology, often by its nature a complex maze.

MAX A. GOLDZIEHER

Infantile Paralysis, Anterior Poliomyelitis. By Philip Lewin, M.D. Octavo of 372 pages, illustrated. Philadelphia, W. B. Saunders Company, 1941. Cloth, \$6.00.

This monograph is a careful and complete review of the disease beginning with a discussion of the bacteriology and ending with ultimate operative procedures. The stress is laid on early recognition and diagnosis and the prevention of deformities. It cannot be called an operative surgery, as the space devoted to the surgical technic is too limited. The work can best be described as a general treatise on infantile paralysis that is of value to the general practitioner and pediatrician.

JAQUES C. RUSHMORE

Play for Convalescent Children in Hospitals and at Home. By Anne M. Smith. Octavo of 133 pages. New York, A. S. Barnes & Company, 1941. Cloth, \$1.60.

This is a well-organized little book designed to outline organized play for children convalescing either in the hospital or at home. Doctors, nurses, parents, or other attendants should receive instruction along the line of play activities for various age groups.

Selection of play equipment and gifts for hospital children's wards are discussed.

The last chapter is especially useful, since it classifies tested forms of play, thus furnishing a guide for those who are to make the selection.

THURMAN B. GIVAN

Fractures. By George Perkins, M.C. Oxon. Octavo of 384 pages, illustrated. New York, Oxford University Press, 1940. Cloth, \$6.50.

This new work by an English orthopedic surgeon will prove to be popular. It is obviously based upon a vast personal experience. As a result, the volume does not read like just another text.

The language is clear and concise. There are many interesting comments concerning the causes, treatment, and healing of fractures. The distinction between consolidation and union, as drawn by the author, is not generally made. Modern procedures in treatment of fractures are thoroughly considered.

The illustrations are simple pen-and-ink drawings. The absence of roentgenograms is regrettable but does not detract from the merits of the book. It is strongly recommended.

MAYER E. ROSS

Proctology for the General Practitioner. By Frederick C. Smith, M.D. Second edition. Octavo of 466 pages, illustrated. Philadelphia, F. A. Davis Company, 1941. Cloth, \$4.50.

Much of the second edition of this book has been amplified and, in part, rewritten. Nineteen halftone illustrations and two color plates have been added, and several new subjects have been introduced, such as a brief consideration of pectenosis. The keynote of the book is practicality, and it is intended as a guide for the general practitioner.

The Table of Contents has been improved by the addition of subheadings under each chapter title.

The book is easy to read both from the standpoint of diction as well as printing. The reviewer recommends it for students and general practitioners.

A. W. MARTIN MARINO

The Biologic Fundamentals of Radiation Therapy. A Textbook. By Friedrich Ellinger, M.D. Octavo of 360 pages, illustrated. New York, Nordeman Publishing Company, 1941. Cloth, \$5.00.

In this book the author presents both an introduction to the study of the biologic effects of radiation therapy and a manual and reference compendium for the use of the general practitioner and radiation specialist.

The biologic effects of x-ray, radium, corpus-

[Continued from page 184]

cular rays, light and ultraviolet rays, and infrared rays are discussed. The experimental basis for those effects is presented meticulously and with great precision and detail. There is an excellent chapter on the theory of radiation effects and, in various parts of the book, detailed presentations of important phases of the subject. The part on radiation changes induced in sex cells is especially well done.

This book is highly recommended to the radiologist for its content and bibliography. Many of the subjects discussed should be of great interest to all physicians.

A. L. L. BELL

The Pharmacology of Anesthetic Drugs. A Syllabus for Students and Clinicians. Second edition. By John Adriani, M.D. Quarto of 86 pages, illustrated. Springfield, Charles C. Thomas, 1941. Cloth, \$3.50.

This syllabus is limited to fundamentals of the pharmacology of the drugs that are used by the anesthesiologist of today. It is of necessity limited in its scope and presents in its context merely an outline of the drugs usually employed in the preanesthetic preparation of the patient, the anesthetic agents used, and the drugs useful in meeting postanesthetic complications. The information is so arranged that the book is extremely readable, and the printed material carries its message with the aid of ingenious drawings and explanatory charts that make dull pharmacology into something really interesting. It is recommended to those who are giving anesthetics, as well as to students of pharmacology and to practitioners of medicine, for in this book is found a presentation of material, a style of writing, and a genius for interesting detail that is not found elsewhere.

F. P. ANSBRO

The American Illustrated Medical Dictionary. A complete dictionary of the terms used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, etc. By W. A. Newman Dorland, M.D. Nineteenth edition. Octavo of 1,647 pages, illustrated. Philadelphia, W. B. Saunders Company, 1941. Cloth. Plain, \$7.00. Thumb-Indexed, \$7.50.

With this revision, Dorland's justly popular dictionary enters its nineteenth edition. As usual, this dictionary is thorough, well edited, and pointed. All of the many recent advances in medicine and chemistry seem to be adequately represented in new definitions intelligently and succinctly phrased.

The many illustrations, while not artistic masterpieces, are accurate and relevant, a virtue that few other dictionaries possess. There are 269 portraits of pioneer scientists and eponyms are thoroughly reviewed. In short, this edition can be recommended to student and graduate physician alike.

MILTON PLOTZ

The Malarial Therapy of General Paralysis and Other Conditions. By William H. Kupper, M.D. Octavo of 155 pages, illustrated. Ann Arbor, Edwards Brothers, Inc., 1939. Cloth, \$2.25.

Malarial therapy in general paralysis is the accepted form of therapy and one that has been time tried and found to be the most effective form of treatment for that condition.

The book discusses all phases of the subject—the historical, the clinical, and the biologic, as well as the therapeutic results obtained. It also gives a comparison of malaria with other non-specific agents used in inducing fever in the paretics. It is an excellent survey of the subject and contains a well-balanced bibliography, giving references to numerous articles on the subject.

It is a valuable little book that supplies a much needed want.

IRVING J. SANDS

Hutchinson's Food and the Principles of Dietetics. Revised by V. H. Mottram, M.A., and George Graham, M.D. Ninth edition. Octavo of 648 pages, illustrated. Baltimore, Williams & Wilkins Company, 1940. Cloth, \$6.75.

This edition has been thoroughly rewritten and the latest material on vitamins and minerals added. The theory of nutrition is well covered, and diets in definite diseases are prescribed. A large portion of the book is devoted to the individual foods and their prescription, preparation, and therapeutic value. Aside from the fact that the author favors the habits of the British Isles, the book as a whole is timely and is recommended as a medical reference.

MORRIS ANT

A Textbook of Dietetics. By L. S. P. Davidson, M.D., and Ian A. Anderson, M.B. Octavo of 324 pages. New York, Paul B. Hoeber, Inc., 1941. Cloth, \$4.25.

The authors recognize the need for closer co-operation between the research worker in nutrition and the clinician. Also they recognize the patient as an individual with individual food habits, individual likes and dislikes, his own family to eat with, and his often limited pocket-book. They have written this book to help the physician bring the results of nutrition research to the benefit of the individual patient.

Much emphasis is placed on the necessity for improvement in "normal" nutrition and the steps that can be taken to affect it. Present defective eating habits, the fact of widespread malnutrition, and low incomes are given their just consideration.

Before touching on diet therapy, the authors devote a section of the book to the physiology of nutrition. This section is well written, completely authoritative, and logically presented. The section on diet therapy is also practical, exact, and thoroughly up to date. The diet lists, however, in the latter part of the book, are based on Scottish food habits and on the foods that are plentiful and inexpensive in Scotland. While this book is highly recommended for use by the general practitioner, it is suggested that he turn to some of the American standard texts for diet lists.

LAST LETTERS

What becomes of undelivered letters? Here is one that but recently came to light and was published for the first time twenty-seven years after the hand that penned it paid the supreme sacrifice in that other world conflict.

* * *

My darling Mother & Family,

If you open this it will be because that which we fear now, has happened, and Brussels fallen into the hands of the enemy. They are very near now and it is doubtful if the Allied armies can stop them. We are prepared for the worst. I have given dear Gracie and the Sisters the chance to go home but none of them will leave. I appreciate their courage and I want you to let the Jem-meths know that I did my best to send Gracie home, but she refused firmly to leave me. She is very quiet and brave.

I have nothing to leave but the £200 in the pension fund which has never been touched and is mine to leave. I wish Mother to have it with my dearest love. It will supply the place of my little quarterly allowance to her. If I can send my few jewels over will you divide them between Flor and Lil and please send Mrs. McDonnell my long gold chain which she gave me and a keepsake to

Marion Hall. I shall think of you to the last and you may be sure we shall do our duty here and die as the women of our race should die.

My dear, dear love to Mother and Flor, Lil, Jack, Longworth and the children. Also to Eveline McDonnell. God bless you and keep you safe.

* * *

The letter was signed—Edith Cavell, and dated the 19th of August, 1914. Before it could be mailed she was taken a prisoner, her belongings confiscated and the letter went with the rest to help fill the archives of the General Office of Administration.

When the Germans evacuated the city in the closing days of the war, the archives were burned, but the commanding officer, on a sudden impulse, had thrust the letter into his pocket. As a self-appointed exile this soldier died years later in Switzerland. When the envelope containing his will was opened, the letter was found within it.

A reproduction of the original was published in the B. W. R. S. *Salute* and scanning the words one finds it easy to understand why the British have been able to take the brunt of aggression for so many months, and why Democracies can take it.

[Continued from page 186]

1940. Octavo of 154 pages, New York, Columbia University Press, 1941. Cloth, \$2.00.

Appropriately titled, this volume contains the lectures to the laity delivered at The New York Academy of Medicine during 1940. Begun five years ago, the talks have been notable for both the speakers and their subjects.

Included in the present series are six essays dealing, respectively, with the inheritance of mental disease, chemical warfare against disease, the story of our knowledge of the blood, the story of the viruses, the ascent from bedlam (a fascinating discourse on the evolution of modern day care of the mentally ill), and the romance of bronchoscopy.

A fine evening's entertainment will be afforded all who read this book.

MAYER E. ROSS

A Practical Manual of Diseases of the Chest. By Maurice Davidson, M.D. Second edition. Octavo of 575 pages, illustrated. New York, Oxford University Press, 1941. Cloth, \$13.50.

The second edition of this excellent work by Dr. Davidson, whose first edition received such extensive and well-deserved approbation, retains all of the worth-while features of the first, but in order to keep abreast of the times parts have been ruthlessly eliminated and new chapters have been added replete with the most recently acquired knowledge.

In contradistinction to most books dealing with diseases of the chest, this one includes much on the subject of pneumonia and the modern chemotherapeutic attack thereon. An excellent chapter has been added on the subject of "Tomography" with excellent reproductions of same. Altogether, it is a thoroughly profitable presentation of its subject, and we unhesitatingly recommend it as a most helpful reference and textbook for student and practitioner.

FOSTER MURRAY

Science and Seizures. New Light on Epilepsy and Migraine. By William G. Lennox, M.D. Octavo of 258 pages. New York, Harper & Brothers, 1941. Cloth, \$2.00.

This book is an attempt to give a concise statement on present-day knowledge of the nature and treatment of seizures (convulsive and headache). The author has spent many years on the subject and is regarded by his colleagues as an authority on epilepsy and allied disorders. He has contributed materially to the elucidation of the problem and has surrounded himself with a group of young and enthusiastic workers who have produced valuable information and contributions to different aspects of epilepsy.

He has been instrumental in the organization of the Laymen's League Against Epilepsy in an effort to combat the existing ignorance and prejudice about convulsive disorders.

The book contains a rather exhaustive survey of epilepsy, and it presents the practical experiences of the past, as well as the most recent methods of examination and treatment.

There is considerable space given to the subject of migraine. The latter is regarded as allied to epilepsy, and the author produces evidence of such kinship. He speaks of migraine as an

epilepsy of the vegetative nervous system and says that epilepsy may be called a migraine of the brain.

The book is a valuable one and will do much in shedding light on this serious and obscure disease.

IRVING J. SANDS

A Guide to Human Parasitology. For Medical Practitioners. By D. B. Blacklock, M.D., and T. Southwell, Ph.D. Fourth edition. Octavo of 259 pages, illustrated. Baltimore, Williams & Wilkins Company, 1940. Cloth, \$4.00.

A fourth issue of this guide within nine years indicates a demand and usage mainly accounted for by its practical scope. Not at all a parasitologic text, animal parasites pathogenic for man are elaborated in useful detail concisely, simply, and with tabulated data picturing the subject from various points of view. The diagrammatic illustrations, particularly those showing life cycles, are noteworthy features. It is an excellent up-to-date manual, serviceable to public health workers and laboratorians, as well as for that group the title stresses.

IRVING M. DERBY

Abdominal Surgery of Infancy and Childhood. By William E. Ladd, M.D., and Robert E. Gross, M.D. Octavo of 455 pages, illustrated. Philadelphia, W. B. Saunders Company, 1941. Cloth, \$10.

As the authors point out, it has been evident for many years that men doing surgery on infants and young children should have special knowledge of this particular field. They do not suggest that the average general hospital be organized with an exclusive specialty of pediatric surgery but insist that general surgeons who do any major work on these young patients take a special interest and training in the problems involved. This informative book clearly defines the difficulties encountered in the limited field of pediatric abdominal surgery. More than this, many ingenious solutions to these problems are shown, as developed by the staff of the Children's Hospital, Boston.

That their material is plentiful is evident from the fact that their experience includes such groups as 765 pylorotomies and 4,133 inguinal herniorrhaphies. More important, by far, is the disclosure that by their experience they have tremendously improved their results. Hedblom, reviewing the literature in 1931, found that 75 per cent of patients with congenital hernia of the diaphragm died before the end of the first month. In the last 13 such cases operated upon at the Children's Hospital, 11 or 85 per cent have recovered. It is beyond the scope of this review to detail the sound plan of procedure which has produced this result.

There are some minor points with which the reviewer disagrees, as, for example, the idea of the authors that the injection of closed hydroceles is dangerous and useless and that operation is much preferable. We wonder if they have tried quinine and urethane. They entirely condemn the Torek orchidopexy and obtain 80 per cent good results with a much simpler one-stage operation.

ON FLUORESCENCE

The light of tomorrow—already illuminating many places of business is still "Greek" to many of us. Not that we expect a patient to ask a physician if it is recommended for reducing eye-strain, but we might know a little about fluorescent lighting perhaps for our own personal interest.

1. Fluorescent lighting provides window-daylight to remote corners of a room.
2. For equal amounts of light, the new fluorescent lamp creates only a half the total heat, or one-quarter the radiant heat of incandescent lighting.
3. Fluorescent fixtures and lamp bulbs cost several times as much as comparable incandescent fixtures and lamps, but—
 - (a) the cost of electricity consumed is lower, and
 - (b) the benefits accruing from proper lighting of working areas is greater.
4. Specifically—195 watts of fluorescent lighting will produce 7,200 units of light as compared to only 3,700 units of light from a 200 watts incandescent lamp.
5. But remember, both fluorescent and incandescent fixtures may waste 50 per cent or more of their light if not cleaned regularly and often.

DO WE READ?

A survey made by a publishing house brought out interesting facts about present day reading.

Anthony Adverse was purchased at \$3.00 per copy by more than 1,500,000 people—in spite of its 1,200-page length. Publication of a popular-price edition brought more than a million more sales of the long book.

How to Win Friends and Influence People is nonfiction but has been sold to 1,230,000 persons and is still selling strong.

The largest monthly magazine has a circulation of more than three million copies and has several close competitors with very near the same reader interest.

Ten million people read the "pulp" magazines regularly.

The sixty-nine national magazines have increased circulation at the rate of one million subscribers each year for the past twenty years.

[Continued from page 188]

The reviewer does not hesitate to recommend strongly the thorough study of this volume by any surgeon doing either much or little pediatric surgery. He also looks forward hopefully to one or more volumes by the same authors on the other sections of this specialty. If they have not yet considered producing more, he hopes they will take kindly to this suggestion.

WILLIAM H. FIELD

Medical Manual of Chemical Warfare. Reprinted by Permission of the Controller of His Britannic Majesty's Stationery Office. First American Edition. Octavo of 104 pages. Brooklyn, Chemical Publishing Company, 1941. Cloth, \$2.50.

The *Medical Manual of Chemical Warfare* is an American edition reprinted from the Great Britain War Office, thereby rendering the volume immediately available in the United States without the delays now suffered in overseas transportation. Appendix III is the third edition of the "Atlas of Gas Poisoning," already widely known. Some of the plates in this section, which are reproductions from the U. S. Army Medical Department Record of the World War, are not in color as in the earlier editions.

The chemical, physiologic and pathologic classifications closely follow the previous English writing authors rather than the continental. The general and historical descriptions are brief and concise. Important additions have been made in caring for casualties because of the wider areas now involved by aircraft dissemination far beyond the range of artillery.

The possibility of the use of arseniureted hydrogen as a chemical warfare agent is considered in Chapter V. Chapter VI considers industrial gases that are not used for warfare purposes but may be encountered under war conditions.

CARL W. LUPO

Clinical and Experimental Investigations on the Genital Functions and Their Hormonal Regulation. By Bernhard Zondek. Octavo of 264 pages, illustrated. Baltimore, Williams & Wilkins Company, 1941. Cloth, \$4.50.

In this book Dr. Zondek summarizes his clinical and experimental observations since January, 1935. The subject of genital function and the various hormones associated with this process is completely reviewed, and many original observations are recorded. He showed that estrogenic and androgenic hormones are readily absorbed and are effective through the skin. He administered large doses of estrogenic hormone to chickens, rats, and cocks, thereby eliminating the somatotrophic and gonadotropic function of the anterior pituitary lobe and produced dwarfism and marked atrophy of the genitals. Moreover, many of the animals, regardless of sex, developed pituitary tumors as a result of prolonged administration of estrogen.

The chapter on the "Fate of Sex Hormones in the Organism" is interesting, while his theory on the "Mechanism of Menstruation" is original.

The monograph contains a large bibliography, and the material is well presented and arranged and employs many illustrations and tables to emphasize the subject matter.

This book should be of interest not only to investigators working along these lines but also to the clinician who is called upon to treat such problems.

MORRIS GLASS

Contact Lens Technique. A Concise and Comprehensive Textbook for Practitioners. By L. Lester Beacher, Sc.D. Second edition. Octavo of 125 pages, illustrated. New York, the author, 1941. Cloth, \$3.50.

This little volume apparently written for the optometrist will doubtless be helpful as a guide to the fitting of the well-known contact glasses. There is a tendency to make this minor procedure sound formidable, but this arises from the apparent need to describe certain details that one would not need to elucidate for those medically trained.

The author says that the use of a local anesthetic is superfluous and, of course, this is so in a mechanical sense; but we doubt if the patient would agree if he had the opportunity to compare a fitting with and a fitting without the use of an appropriate anesthetic.

The section on buffer solution is not well presented, and the author does not discuss all the dangers and advantages sufficiently. He even suggests the use of distilled water which, of course, is not well tolerated by the eye. He should recognize the therapeutic aspects of buffers and discuss their biologic effect and purpose. It seems a bit unusual in a scientific work on technic to insert a section on "Fees." Perhaps this is technic also.

Though this is doubtless useful, its reliability is greatly limited by the fact that the only bibliography is that of the author, and much of this does not refer to contact glasses. A voluminous literature has appeared on the subject in the last fifteen years to which the author has made no reference.

JOHN N. EVANS

A Primer for Diabetic Patients, An Outline of Treatment for Diabetes with Diet, Insulin and Protamine-Zinc Insulin. Including Directions and Charts for the Use of Physicians in Planning Diet Prescriptions. By Russell M. Wilder, M.D. Seventh edition. 16 mo. of 184 pages. Philadelphia, W. B. Saunders Company, 1941. Cloth, \$1.75.

This small practical book is designed to help those suffering from diabetes, as well as those interested in the subject.

The book is written in a clear, concise manner. It is presented in nine sections in which the nature of diabetes is explained; the necessity for the various forms of insulin is stated, and many facts are presented which allow a clear understanding of the subject. In particular, complications or disturbances apt to occur in the diabetic patient are discussed and presented in a clear fashion. Diets and diet recipes are explained.

This revision was necessitated to describe an improvement in the procedure of administering protamine-zinc insulin. It is recommended highly for the intelligent understanding and knowledge it conveys to the diabetic patient.

War Surgery

The proper care of war injuries—trauma of every description, damage by poisonous gases, and burns of all kinds—is now a matter of immediate importance. The success of treatment must be gaged not only by preservation of life and function but also by economy of effort and hospitalization.

War medicine and war surgery must be geared to this point of view. Proper care means the best of immediate treatment in order to prevent unfortunate and unnecessary sequelae and to avoid prolonged hospitalization for reconstructive measures.

To accomplish this, the Council Committee on Public Health and Education is now taking immediate steps to provide instruction, both didactic and clinical, in war medicine and war surgery—especially plastic and reconstructive surgery—as part of its postgraduate instruction for the current year. Some of the technics of such surgical care, both immediate and later, are new, and many physicians are not familiar with them either for their own use or for rapid recognition of condi-

tions that should be referred to specialists in these technics. This care presupposes the highest quality of first aid and also proper preparation of injured tissues for later surgical procedures.

We are now engaged in what should rapidly develop into an offensive war. This will undoubtedly be accompanied by enemy attacks on the continental United States in the course of time. Last year, in anticipation of the eventual necessity, a plan was proposed for offering instruction in plastic and reconstructive surgery as part of the medical preparedness program of the Medical Society of the State of New York. As a result of this foresight, eighteen well-qualified surgeons quickly responded to the request for their services as teachers.

The Society is, therefore, fortunate in that having foreseen the probable necessity for increased instruction in plastic and reconstructive surgery and set up the teaching facilities it will be possible to expand these courses rapidly now that war conditions make this imperative.

Delayed Registration Certificates

Many physicians may not yet have received their 1942 certificates of registration from the Department of Education. The JOURNAL has had some inquiries about the delay. We are informed under

date of January 9, 1942, by Dr. Joseph S. Lawrence, executive officer of the Society, that "the Department of Education is doing its utmost to supply the physicians with their 1942 registration certificates

but has been greatly delayed, first by the installation of new recording machines, and now by a lack of clerical service.

"Physicians who have applied for re-registration are assured that they will receive their certificates at an early date, and in the meantime they need not fear that they are violating the law by continuing their practice."

The Department of Education has asked that this information be conveyed to the physicians of the state, and we bespeak the tolerance of those who have not

received their certificates. It is probable that conditions due to the war, restriction and reduction of operating personnel arising from the new Selective Service demands, and other unpredictable conditions will make it difficult for many departments to maintain their otherwise prompt and efficient service to the physicians of the state. The delays will, however, be accepted with patience and good nature and with a real appreciation of the efficiency with which these services have been maintained in the past.

Fewer Tires, Fewer Fatalities?

The recent restrictions on the sale of new rubber automobile tires may have some interesting results in 1942. What, for instance, will be the effect of the rationing upon the motor-vehicle accident deaths? The deaths from this cause in 1941 were about 39,500¹ or more than 14 per cent as compared with 1940, a gain of about 5,000 deaths over the previous year. In the same period, "data now available indicate that there may be some 1,500 more fatal accidents to persons at work in 1941 than in 1940." This rise in industrial fatalities might have been anticipated because of the greatly increased industrial activity throughout the year 1941. But the increase in motor-vehicle accident deaths for the same period seems to be inordinately large. It is now alleged that for "more than a decade... motor-vehicle fatalities have been the leading class of fatal mishap."

¹ Statistical Bulletin, Met. Life Ins. Co. 22: No 12, 9 (Dec) 1941.

Will the restrictions now in force relating to the use of new tires for automotive vehicles affect the accident total for 1942 and, if so, how? By decreasing the volume of traffic, it would be anticipated that these restrictions would tend to reduce the total. On the other hand, it is possible that the forced use of worn-out treads or recapped casings may increase the severity of those accidents that do occur and thus considerably raise the number of fatalities. This is the more probable since it seems inevitable that crowding of many vehicles will occur as fewer tires of any kind become available.

Until satisfactory substitutes for rubber make their appearance, more careful and considerate driving will, we hope, help to reduce the highway accident toll. It may not be too much to hope that some of the safety habits acquired during this period of tireless tranquilization may survive it. The figures will show.

Federal Regulation of Insulin Standards

On December 24, 1941, the protection to users of insulin afforded by control of the product by the University of Toronto ceased through expiration of the patent.

However, on December 22, 1941, the President of the United States approved H.R.6251 (Public Law 366), a bill to

amend the Federal Food, Drug, and Cosmetic Act by providing for the certification of batches of drugs composed wholly or partly of insulin. The necessity for the legislation stemmed from the expiration of the insulin patent held by the University of Toronto under which standards of

purity and strength of insulin have been adequately maintained. Under the new law the Federal Food, Drug and Cosmetic Act is so amended by Section 1 that its prohibitions against "forging, counterfeiting, simulating, or falsely representing, or using identification devices without proper authority, will apply in the case of such identification devices as may be required or authorized for insulin." Section 2 of the amended Act provides that a drug shall be misbranded "if it is, or purports to be, or is represented as a drug composed wholly or partly of insulin, unless (1) it is from a batch with respect to which a certificate or release has been issued under regulations to be promulgated by the Federal Security Administrator and (2) such certificate or release is in effect with respect to such drug."

Section 3 directs the Federal Security Administrator to establish standards of purity, quality, identity, and strength for

drugs composed partly or wholly of insulin; to determine and set out in regulations schedules of fees which will cover the cost to the Government of equipping and maintaining the facilities and compensating the personnel required for making adequate tests and assays. Section 4 directs the promulgation of these regulations within forty-five days.

Provision is made also in Section 3, for the release by the Administrator prior to the promulgation of regulations, of insulin which, in the Administrator's judgment, may be released without risk as to safety and efficiency. This permits him to release for prompt use batches of insulin which have already been passed by the Insulin Committee of Toronto University. Any risk of a shortage is thus avoided with safety for the more than 1,000,000 users in the United States, who spend for it annually some \$15,000,000.

Common Sense

The Nassau Medical News¹ comments on nutrition:

Forty-five million people in the United States "lack the foods we know are essential for health . . . another 50,000,000 have impaired health because they do not eat the right food." Thus does Dr. Logan Clendenning in a recent issue of the *J.A.M.A.* quote Paul V. McNutt, coordinator of health, welfare and related defense activities.

Mr. McNutt's statement as quoted above falls into the category of one of those things. It is general, comprehensive, arresting, and conveniently quotable. It is positive. It conveys the impression that, in Mr. McNutt's mind, there is no shadow of doubt that this is so. The presumption is that he has information on this matter of which he does not question the source or the reliability. If he did, presumably he would not have made the statement or would at least have qualified it.

The statement was apparently made for the purpose of informing the public of something which the public ought to know. It contains a diagnosis: "50,000,000 people have impaired health because they do not eat the right food." No ifs, ands, or buts about that, is there? Another 45,000,000 "lack the foods we know are essential for health." This seems to be a severe, possibly an unintentional, criticism of an administration that has been distributing agricultural surpluses to the needy for a long time. And is it possible that the slaughtering and plowing under of many products of the farm could have anything to do with the "lack of foods we know are essential for health?"

It is perhaps more comprehensible if we employ the device of *hysteron proteron*² in Mr. McNutt's behalf. If, say, "50,000,000 people have impaired health because they do not eat the right food," they and another 45,000,000 do so be-

¹ Food—Eat It or Take It 15: No. 10 (Nov.) 1941.

² Cart before the horse.

cause they "lack the foods we know are essential for health," then we may inquire: why? There must be a reason. Is the Administration's farm policy being called in question by the Coordinator of Health, Welfare and Related Defense Activities? Or is there some reason other than this, as yet undisclosed, why the head man of the Security Administration is all at once concerned with the impaired health of 95,000,000 potential voters?

The Nassau Medical *News* says that:

"Dr. Clendenning doubts these figures and counters with the report that out of some 338,000 hospital records studied he found only 483 patients recorded as coming within the medical understanding of 'impaired health because they do not eat the right food.'"

We are relieved to learn that the effects of the Administration's policy of scarcity are not quite so bad as Mr. McNutt fears and that the public's eating habits are not so bad as they are implied to be.

"The National Nutrition Conference," says the Nassau Medical *News*, "drew up a nutritional 'gold standard' which would

include: one pint of milk for an adult and more for a child (evaporated milk may be used instead of fresh); a serving of meat (cheaper cuts are just as nutritious); one egg or some suitable substitute such as navy beans; two vegetables, one of which should be green or yellow; two fruits, one of which should be citrus, tomato, or similar (canned orange juice is the cheapest source of vitamin C); some butter or oleomargarine with vitamin A added; breads, flour, and cereal, preferably whole grain or enriched.

"If the daily diet stays on this gold standard and the individual develops a vitamin or mineral deficiency, it is safe to say that the problem is one for the physician to solve, not for the radio announcer, the newspaper advertiser, or the street corner health advisor.

"It is not only safer but very much cheaper to eat your food rather than take it in the form of pills, powders, or capsules. Consider the vitamin concentrates as medicine and take them only on the advice of your own doctor."

Correspondence

American Congress on Obstetrics and Gynecology

To the Editor:

In this time of stress there should be a definite interest in the welfare of the mothers and babies of the nation. The Committee that is sponsoring the next American Congress on Obstetrics and Gynecology, to be held in St. Louis on April 6 to 10, 1942, represents the only organization outside of governmental bodies which has attempted to unite the efforts of voluntary and other agencies to carry out the widely disseminated plans for the care of women and children. Opportunity for the presentation of advances in obstetric and gynecologic knowledge will be afforded to the many groups interested in these

problems at a nation-wide gathering of this kind. The directors of the project believe that notwithstanding the war situation the Congress should be held at the stated time and are proceeding with their plans to make of this an outstanding gathering. Further details of the program will be communicated as these are made available. Inquiries may be addressed to the Central Office, 650 Rush Street, Chicago.

Symposium on Pyelonephritis

THE EFFECTIVENESS OF THE SULFONAMIDES ON THE BACTERIA ENCOUNTERED IN INFECTIONS OF THE UPPER PART OF THE URINARY TRACT

ROSCOE C. BORST, M.D., F.A.C.S., Utica, New York

PRIOR to Domagk's discovery of prontosil and its effective treatment in staphylococcal and streptococcal infections eight years ago, the chemotherapy of systemic bacterial diseases was disappointing.

During the intervening time, sulfonamide derivatives have been introduced which are highly effective against systemic bacterial invasions. This period has been called "epochal in the history of medicine." The volume of observations and reports is enormous and rapidly increasing. Frequently, these are speculative and of little value; hence, it appears that a study and survey of the efficiency of the sulfonamide compounds in urologic infections may be helpful.

History

Thirty-four years ago Gelmo synthesized sulfanilamide, but its therapeutic value was neither suspected nor studied.¹ In 1932 Domagk's investigations in the preparation of azo dyes with the sulfonamides resulted in the production of a substance that was introduced to the world one year later by Dr. Foerster as prontosil. This in the opinion of many observers constitutes the greatest therapeutic discovery in modern medicine and relegates salvarsan to second place.

In 1936 Nitti and Boret found that prontosil was split by the tissues to liberate sulfanilamide—the chemotherapeutic portion. This preparation was not patented and led to the production of a great number of new derivatives. Many manufacturers unwisely exploited their products, requiring the Council of Pharmacy and Chemistry to untangle the existing confusion by recognizing only proved derivatives.

Sulfapyridine was presented to the profession in 1938 and sulfathiazole followed in the ensuing year. Previous to the introduction of these, pyridine and serenium made their appearance as urinary antiseptics—the former in 1926 and the latter in 1930.

Fortunately, the present Food and Drug Act has required all the derivatives of sulfanilamide, with the exception of the "elixir of sulfanilamide," to have a substantial investigation and application. The Council of Pharmacy and Chemistry of A.M.A. has recognized only three of these—namely, sulfapyridine, sulfathiazole, and sulfadiazine. Another, by the time this article is printed, will be accepted—namely, sulfaguanidine.

The sulfonamide drugs are: prontosil, sulfanilamide (prontylin), neoprontosil, sulfapyridine (dagenan, M and B 693); sodium sulfapyridine, sulfathiazole, sodium sulfathiazole, sulfamethylthiazole,* sodium sulfamethylthiazole,* sulfadiazine,* sodium sulfadiazine,* sulfaguanidine, dodeconoyl sulfanilamide.*

Mechanism of Action

Numerous theories have been advanced to explain the mechanism of the antibacterial action of the sulfonamide chemicals. At the present writing the most accepted theory has been advanced by Long and Bliss.³

During the process of invasion, bacteria have a natural oxidative action in the tissues which creates the formation of hydrogen peroxide. This is removed normally by the catalase present in the blood and tissues. The oxidation of the sulfonamides inhibits this catalase action preventing the hydrogen peroxide removal. It thereby accumulates in the tissues and either inactivates or destroys the bacteria.

Since all of the sulfonamide derivatives are not equally effective on all types of bacterial infections, it at once becomes obvious that the proper selection is of the greatest importance. This obviously requires accurate bacteriologic study and isolation of the specific invading organism.

The question of the volume of fluid intake with cases receiving the various sulfonamide derivatives is of the greatest importance.

* These drugs are under investigation.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

Inadequate blood concentration will be obtained if more than 3,000 cc. of fluids each twenty-four hours is taken when prescribing sulfanilamide. This drug does not directly damage the kidneys.

When sulfapyridine or sulfathiazole is being prescribed, the administration of greater fluid intake is a necessity. This is due to the fact that in too concentrated urines the precipitation of the insoluble acetyl sulfapyridine or the nonsoluble acetyl sulfathiazole will occur. This creates tubular blockage and becomes the precursor to renal calculi formation. Therefore, the urine output should be kept at 1,000 cc. or more for each twenty-four hours. The presence of these crystals in voided urine is never an indication for stopping the drug. The appearance of gross hematuria, however, is a frank indication.

The acetylated form is a severe hindrance. It is created by the liver in conversion from 10 to 60 per cent of the total amount of the drug administered and yields toxic derivatives. The crystals may be precipitated out, as previously stated, to mechanically block the kidney tubules and form concretions.

The elimination of food with a high sulfur content, as well as the sulfates, has been too severely stressed. Long states that "there is not a bit of data available which would lead one to believe that such a superstition has any foundation in fact." The exception is the use of the present intravenous anesthetics containing barbiturates—not the sedatives.

Prophylactic Value

In those cases where there is danger of a rapid spreading of infection—such as post-operative peritonitis, cellulitis, pyelonephritis following pyelotomies, nephrostomies, cystotomies, and other surgical procedures where infection may be introduced into healthy nonresistant tissue—the sulfonamides have prophylactic value. This requires establishment of effective blood concentration of the drug over a brief period and is entirely dependent upon their rates of absorption and excretion.

Prontosil in aqueous suspension and sulfanilamide in oily suspension are absorbed and excreted slowly when injected subcutaneously. Hence, their prophylactic value is excellent. If, however, the prontosil is given by mouth, its value is less marked and nil with sulfanilamide. Therefore, with slow absorption and excretion prophylactic value is good; if the reverse is true, it becomes slight.

As each derivative has been introduced,

desirable information pertaining to its absorption, distribution, action, excretion, and toxic effects it possesses has been studied.³

Successful therapy depends upon the maintenance of a definite concentration of the drug in the blood. The choice of the derivative to be employed in a given infection should be accurately selected. Also, it is imperative to know that drug's behavior in the body, as well as its effectiveness.

Sulfanilamide when injected is well absorbed from the gastrointestinal tract, equally distributed throughout the body tissues, and properly excreted with normal renal function. Even in renal damage it is well eliminated.

Sulfapyridine is irregularly absorbed by different individuals and by the same individual. It is fairly well distributed throughout the tissues and conjugated by the liver to the inactive acetyl derivative in a higher degree than either sulfanilamide or sulfathiazole. Sulfapyridine is excreted by the kidney more slowly than either sulfanilamide or sulfathiazole and appears in the practically insoluble acetylated form, where it crystallizes out.

Sulfathiazole is rapidly absorbed and rapidly excreted when kidney function is normal. If renal function is decreased, preventing elimination and thereby retaining the drug in the body over a period beyond normal, its rate of conjugation increases. The drug is excreted so rapidly by the kidney that conjugation⁴ cannot be complete and, therefore, is not converted in large amounts to the acetyl form. Adequate blood concentration, therefore, is difficult to maintain, and an inefficient therapeutic effect may result. The spinal fluid absorbs lesser amounts of the drug than either sulfanilamide or sulfapyridine, and this absorption is inadequate for efficient bacteriostatic effect in all of these. Sulfadiazine, fortunately, is absorbed in the spinal fluid in sufficient concentration to be therapeutically active.*

Urinary Infections

Successful treatment of urinary infections may require concentrations in the urine of the free drug as high as 300 mg. per hundred cubic centimeters for approximately seven days. With unimpaired renal function, this may be maintained by controlling the daily ingestion of both the drugs and fluids.

The sulfonamides actually produce bactericidal action in many urinary tract infections when the hydrogen ion and drug con-

* Dr. Norman Plummer.

centrations are optimal. This is due to the fact that urine concentrations are reached which are ten to forty times higher than those attained in the blood. Then, too, the urine is a poor medium for bacterial growth. This combination of poor environment and high concentrations results in bactericidal action not procurable in other tissues.

The intelligent use of the sulfonamides is based more on bacteriologic than clinical diagnosis, and their indiscriminate use without the former obviously should be discouraged. This fact becomes more impressive as we continue.

While antibacterial action may occur in all hydrogen ion concentrations, better results are obtained with a pH value of 7.0 or 7.5. It may be necessary, therefore, to combine an alkali such as sodium bicarbonate (3 to 5 Gm. per diem) with each dosage. The exception is with *Streptococcus fecalis*, where a lower pH value is more effectual. Alkaline urine in itself, as it is formed in the body, is neither bactericidal nor bacteriostatic.

We have come to learn through trial and error that frequent complicating urologic lesions will modify progress and results with these drugs. Purulent foci must receive adequate attention lest the bacteriostasis leads to false security, since recovery appears symptomatically complete only to relapse with the drug's withdrawal. This inhibition of the acute invasive manifestations is preceded by the reinvasion of the tissues from hidden foci. These deep-seated infected areas and pockets, created particularly by stasis, lithiasis, chronic pyelonephritis and pyohydronephrosis, ureteral and bladder obstructions, diverticula, and localized renal abscesses, become the major problem with those cases, having repeated exacerbations and retarding or preventing complete eradication.

One is able to estimate accurately the urinary concentration of both the free and conjugated forms of sulfanilamide, sulfathiazole, and sulfadiazine when the daily dose and fluid intake are known. As an example, since approximately 90 per cent of the drug is excreted in the urine, 4.5 Gm. will be excreted with a dose level of 5.0 Gm. ingested. Assuming a urinary output of 1,000 cc. in twenty-four hours (fluid intake of about 1,500 cc.), the concentration in the urine will be 450 mg. per hundred cubic centimeters. Inasmuch as half of the excreted drug is in free form, the concentration of the free portion will be approximately 225 mg. per hundred cubic centimeters.

Excretion

The ability of the kidneys to excrete the sulfonamides should be determined by the phenolsulfonphthalein excretion test whenever necessary. Since more than 93 per cent of the drug is eliminated through the renal parenchyma, poor kidney function would delay the excretion sufficiently to create a toxic state in an otherwise safe dosage. Long and Bliss gave a single dose of sulfanilamide to a uremic patient and found no variation in the blood concentration during a seven-day observation period.

Normally, the drug is rapidly eliminated with adequate fluid intake and renal function unimpaired. No host is entirely free of the drug within three days.

Toxic Manifestations

Only the important toxic manifestations created by the sulfonamide derivatives will be discussed in this article. A complete summary of this phase of the work may be obtained in the monograph by Long and Bliss.³

A wide variety of toxic reactions are produced with therapeutic doses. It is important to recognize these symptoms and to differentiate them from the illness itself. The federal control of the sale of these drugs represents a commendable advance in the protection to the public against their indiscriminate use.

Nearly all patients receiving the sulfonamides experience mild toxic reactions which usually appear within the first forty-eight hours and particularly so if the case is ambulatory.

The milder manifestations of toxicity are not necessarily the precursors to the more severe symptoms, because the latter depend almost exclusively on high blood concentrations from excessive dosage or idiosyncrasy.

The mild nausea and vomiting commonly observed may be partially alleviated or totally abolished by the use of nicotinic acid, giving 50 mg. with each dose. More uniform results have been observed with the employment of mucilage of tragacanth (made fresh daily) by adding a dram with each dose of the drug. I have found that the use of citric acid, 14 per cent, combined with sodium citrate, 9 per cent, prescribed in dram doses and administered with the drug serves the double purpose of allaying the vomiting and also relieving and preventing acidosis.

The more important toxic manifestations are shown in Table I.

TABLE 1.—SULFONAMIDE THERAPY—TOXIC REACTIONS

Blood	Gastrointestinal
Anemia	Nausea and vomiting
Simple	Dehydration
Acute hemolytic	Acidosis
Aplastic	Diarrhea
Leukopenia	Dehydration
Granulocytopenia	Acidosis
Agranulocytosis	Skin—Drug Rash
Hyperleukocytosis	Purpura
Cyanosis	Morbilliform
Liver	Erythema
Hepatitis	Scarlatiniform
Jaundice	Erythema nodosum
Kidney	Nervous System
Hematuria	Neuritis
Colic-loin pain	Headache
Anuria	Psychosis
Calculus formation	Mental depression
Nitrogen retention	Delirium
Uremia	Drug Fever

The more serious effects of these derivatives are related to the blood, bone marrow, and the skin. Blood counts should be done every other day to recognize in its inception the sudden developing anemia or the change in the number or character of the white blood cells. Granulocytopenia may occur as late as six days after the drug has been discontinued.

The prescribing of the barbiturates during sulfonamide therapy is not dangerous for the host, but pentothal sodium as an intravenous anesthetic is contraindicated since definite injury to the liver may follow.

These chemotherapeutic drugs vary greatly in their production of toxic symptoms. Of the several discussed, sulfapyridine is the greatest offender, and toxic manifestations may be expected to occur four times more frequently than with sulfanilamide. Sulfathiazole is less toxic than sulfanilamide, and sulfadiazine is decidedly less toxic than either of these. Because of the low degree of absorption of sulfaguanidine, no toxicity has been observed. This drug, however, has yet to receive a broad use. Cutaneous eruptions appear more commonly after sulfathiazole than the other derivatives and carry with them a high incidence of conjunctivitis.

Contraindications

Because of the mad rush to introduce or prescribe the sulfonamides and their derivatives, a thorough and complete study of this phase of the pharmacology has not been completed. However, I will state that the drug should be withheld from patients who have shown an idiosyncrasy or sensitivity to previous sulfonamide therapy. Also, these drugs should not be prescribed to patients

having a severe anemia, leukopenia, hepatitis, or extensive renal damage.

The sulfonamides differ in several important respects from mandelic acid. Each of these preparations have their separate indications and supplement each other.

Sulfonamides have the advantage that they are effective at all urinary pHs but are decidedly more active in an alkaline urine. Mandelic acid is effective only in distinctly acid urines and with undamaged renal tissue.

Sulfonamides are cheap but toleration varies. It may be administered by more than one route, whereas the acid can be taken only orally. Sulfonamides do not provoke acid base, balance disturbances, which is a distinct advantage in acutely ill and febrile patients and those with impaired renal function. The sulfonamides clear urinary infections caused by urea-splitting organisms, such as *Bacillus proteus*, which are unaffected by mandelic acid. It is effective against *Str. fecalis* whereas the sulfonamides fail, although, recently, Helmholz has shown that sulfathiazole has considerable bactericidal action against this organism. Sulfadiazole and sulfadiazine frequently are excreted in sufficiently high concentration by impaired renal tissue to be bactericidal.

Tables 2 and 3 show the organisms upon which sulfanilamide and mandelic acid are effectual.

How impressive the literature is on the dangers of sulfonamide therapy in the presence of depressed renal function and increased blood nitrogen. But it has not impressed us on the efficiency of these drugs in small doses with the kidney function below par. To be sure, extremely careful observations

† Refer to Table 4.

are required and good judgment and frequent blood readings are essential in the control of infection and in preserving renal tissue.

There is Helmholtz's⁵ spectacular result in a 16-year-old boy who had been under observation for seven years and who eventually had the infection cleared from the urinary tract. The case had bilateral, infected hydronephrosis, megaloureters, a huge dilated bladder, and a posterior urethral obstructing value. During the interval, his weight increased from 52 to 106 pounds and the blood urea concentration increased from 60 to 160 mg. per hundred cubic centimeters. During 1939 his urea concentration was never less than 150 mg. with the urine clear and a minimal number of bacteria. Of the sulfonamides, sulfanilamide was selected and prescribed in a dosage sufficient to maintain a concentration ranging from 16 to 42 mg. per hundred cubic centimeters of urine. With this technique the urine cleared of *E. coli* infection for three days, only to return immediately. Sulfathiazole therapy was substituted in November, 1940. On a dosage of 4 grains, six times daily, the *E. coli* infection disappeared and was replaced with pseudomonas. That dosage became intolerable during February, 1941, and was reduced to 2 grains twice a day. This was well tolerated and, surprisingly, the urine became clear with only a minimal number of bacteria present. Such results are encouraging, since the conservation of renal tissue is the *sine quo non* in such patients.

This observation plus further experimental work by Helmholtz shows sulfathiazole decidedly superior to sulfanilamide as a urinary antiseptic in concentrations from 10 to 30 mg. per hundred cubic centimeters of urine and makes possible the effective use in cases with damaged kidney tissue. Oral doses as low as 5 to 10 grains per diem render surprisingly satisfactory results.

This work, which is summarized in Table 4, is impressive.

Sulfathiazole

This drug, which was introduced in 1940, is of great interest to the urologist since it is more effective than sulfanilamide and sulfapyridine in the treatment of infections of the urinary tract.

It is rapidly and quite adequately absorbed from the intestinal tract and is much less toxic and well tolerated by the oral route, rarely causing gastric distress.

As its fate and excretion are quite similar to

TABLE 4.—SULFATHIAZOLE

Staph. aureus	7.5	7 mg./100 cc. in 75 per cent of cases	25
Proteus ammoniae	7.5	25 mg./100 cc. in 94 per cent of cases	150
Str. fecalis*	5.5	50 mg./100 cc. in 58 per cent of cases	300
Ps. aeruginosa		Hydrogen ion concentrations of little value	300
A. aerogenes	7.5	25 mg./100 cc. in 90 per cent of cases	Not procured
E. coli	7.0	25 mg./100 cc. in 60 per cent of cases	200

* Refer to Table 3.

sulfanilamide, this phase will not be discussed. It is advisable to draw attention to the relative insoluble acetylated forms (being three times less soluble than acetyl sulfanilamide), which may precipitate out, in the renal tubules and the urinary tract.

Sulfathiazole has shown its bactericidal effects in practically all types of organisms which invade the urinary tract. Its greatest benefit lies in its superior antibacterial action on staphylococci and on *Str. fecalis*. As with the other sulfonamides, complicating co-existing pathologic processes in the tract decrease its efficiency, particularly those creating stasis and obstruction. The percentage of the total amount of sulfathiazole present in the urine as acetyl sulfathiazole ranges between 10 and 30 per cent. This percentage is lower than those for sulfapyridine and sulfanilamide. The free form (active bactericidal) is not so freely excreted as sulfanilamide by damaged renal tissue.

Sulfapyridine

Because of its relative insolubility, sulfapyridine is absorbed from the intestinal tract at a much slower rate. Like sulfanilamide, it is acetylated in the body. The amount, however, is unpredictable and tends to run higher so that the dosage necessary for optimal blood levels of the active free portion cannot be made uniform. This drug is excreted at a much slower rate than sulfathiazole, tending thereby to a cumulative toxic quantity and requiring caution with impaired renal function. The more active the renal infection, the quicker will renal complications develop with this derivative.

Complications of Sulfapyridine

The renal complications associated with

FIG. 1.

sulfapyridine are dependent on two factors: first, the precipitation of the crystals; second, the oliguria.

Because of the poor solubility of the conjugated derivatives, crystals precipitate out of the urine and lodge in the renal tubules, pelves, ureters, and bladder. Renal function becomes impaired by this mechanical plugging and complete anuria follows. These complications require daily microscopic examination of the urine. Cystoscopic manipulation and ureteral lavages have been necessary to loosen these crystals.¹³

The crystals that may be precipitated from both an alkaline and acid urine consist of about 70 per cent of the insoluble conjugated form rather than the free sulfapyridine. They are not opaque to x-rays but will create negative shadows. The rate of precipitation cannot be altered by prescribing alkalis. The crystals appear in irregular friable white masses. Microscopically, the crystals are colorless, flat, thin plates, are pointed or wedge-shaped, and are joined together in triangular bundles.

Hematuria occurs in 25 per cent of all cases and children are more prone to develop renal complications.

At this point it is fitting to state that because of the uncontrollable damage sulfapyridine may create it should have no place in the urologists' therapeutic armamentarium. The other sulfonamide derivatives, as have been mentioned, have greater efficiency and

FIG. 2.

are much less injurious to the renal parenchyma.

In the same voice, the urologist must be acutely aware of its dangers. He should be accurate in recognizing its damaging and destructive effects and quick to remove the mechanical obstructive material.

Newer Drugs

Within the past two years new sulfonamide derivatives have been drawn to our attention. Two of these, sulfadiazine and sulfaguanidine may be destined to become the Utopia in the urologists' therapeutics. Definitely, they will replace the earlier developed preparations.

Sulfadiazine

Sulfadiazine was synthesized by Roblin, Williams, Winnek, and English,⁶ and the experimental animal data pertaining to toxicity, absorption, and chemotherapeutic activity were completed by Feinstone, Williams, Wolff, Hunington, and Crossley.⁷

The excellent study of the absorption and excretion of sulfadiazine by Plummer⁸ has done much to stabilize its dosage and demonstrate its efficacy.

The comparative blood levels after a single 2-Gm. dose between sulfathiazole, sulfapyridine, and sulfadiazine are shown in Fig. 1. This figure shows that sulfadiazine is rapidly absorbed and that a higher blood concentration is reached than with either sulfathiazole or sulfapyridine with the same dosage.

Traces of the drug remain after forty-eight hours showing a slower renal excretion than either sulfapyridine or sulfathiazole.

In another series, 2 Gm. of sulfadiazine was administered as an initial dose, followed by 1 Gm. every four hours until a total of 16 Gm. had been given.

Fig. 2 shows the blood level of sulfadiazine to be higher than either sulfapyridine or sulfathiazole. The blood level fell slowly after the drug was discontinued, and even at the end of forty-eight hours there still remained a trace of the drug.¹

The total amount of the excreted drug reclaimed in the urine ran as high as 12.7 Gm. out of a total of 16 Gm. ingested. Such an amount compares favorably with the other drugs in this group and is proof that over 90 per cent is excreted by the kidneys.²

In this same series no kidney irritation was demonstrable. Renal function tests and blood nitrogen and urea always remained within normal limits. Neither gross nor microscopic blood appeared and the tests for albumin were negative.¹⁰ The stomach tolerated the drug exceedingly well; the dreaded annoying symptoms of nausea and vomiting did not occur.

For its distribution in the body, reference is directed to Reinhold, Flippin, and Schwartz's article in the *American Journal of Medical Sciences*.⁹

Toxic effects simulate sulfanilamide, sulfathiazole, and sulfapyridine but to a much lesser and milder degree. Dermatitis and vomiting have been observed but in infrequent occurrences. As a contrast to the other sulfonamides, it can be said that the development of toxic manifestations is not expected when used within proper therapeutic ranges.

Sulfadiazine is absorbed rapidly from the intestinal tract, and effective blood concentrations are reached within two to four hours. Like its sister compounds, the elimination is over 90 per cent through the kidneys. Its excretion develops slowly but within forty-eight hours reaches amounts comparable to the others. Therefore, because of efficient absorption and its early relatively low rate of excretion, smaller doses are required to maintain a given blood concentration. It is more soluble than sulfanilamide, sulfapyridine, or sulfathiazole, with a greater percentage of the active free drug present in the blood stream. The crystals of both the acetylated derivatives and the free form are extremely soluble so that renal damage is nil. The drug appears active to a bactericidal degree in undamaged renal tissue. It is eliminated without renal injury in at least bacteriostatic concentrations by the damaged kidney. Preliminary observations have shown encouraging results in infections of the upper part of the urinary tract created by the colon group of organisms, *Str. fecalis*, and *proteus*.

FIG. 3. Sulfadiazine crystals.

A photomicrograph of the sulfadiazine crystals is shown in Fig. 3. They appear as many short fine strands tightly bound together in a central stalk branching out broadly like a treetop with the other extremity less broad and smaller.

Sulfaguanidine

Little data are available pertaining to this drug. The enthusiasm shown by the original workers is sufficient¹¹ for me to draw it to your attention.

The drug's solubility is approximately 2 per cent, thereby being nontoxic. Its merit lies in its ability to act as an intestinal antiseptic or at least prevent the passage of the coliform group of organisms from the bowel to the upper part of the urinary tract.

It has been shown quite conclusively by Kretschmer, Williams, Smith, and others that the course of infection in pyelitis of pregnancy is by the way of the lymph stream from the large bowel.

By the beginning of the fourth month of pregnancy a muscular atony of the upper part of the urinary tract becomes established.¹² This is created by the hormone prostigmin, which is instrumental in the creation of a similar condition in the uterus, bowel, and gallbladder. Constipation develops, and the mucous membrane of the bowel becomes permeable to bacteria and, by their lymphatic absorption, are carried to the "physiologic hydronephrotic kidneys and hydroureters" of the pregnant woman.

The action of sulfaguanidine is an intestinal antiseptic one or has a specific destructive action on the coliform group of bacteria. When administered early in pregnancy, infection of the upper part of the urinary tract fails to develop. If once established, it is more readily controlled with sulfaguanidine.

It takes no imagination to visualize a broader use for such a drug in preventing those destructive renal lesions which so commonly follow pregnancies. Control of the hypertensive states associated with pyelonephritis also becomes possible. Its prophylactic use in intestinal surgery may fulfill many expectations. These are a few of the many possibilities hoped for by this drug.

Sulfaguanidine crystals are colorless. They consist of many fine needle-shaped fibers usually thrown together in parallel strands or radiating from a common center.

Conclusions

1. No single drug has been discovered which may be used for all types of urologic bacterial infections.

2. The urinary antiseptic that can be excreted in bactericidal concentration by a damaged kidney is not known.

3. Rapid excretion is a great advantage in the use of these drugs as a urinary antiseptic, since a low blood level will create the same urinary concentration as obtained with a high

blood level and a less rapid renal elimination.

4. Sulfapyridine is the most toxic of the sulfonamide derivatives and has no place in the therapeutics used by urologists.

5. Sulfathiazole in extremely small doses is effective as a urinary antiseptic when renal function is impaired.

6. As sulfathiazole has a better bactericidal action in lower concentrations than either sulfanilamide or sulfapyridine on the more common organisms of urinary infections, and has a more active one on *Str. fecalis*, therefore, it becomes the drug of choice of these three.

7. Sulfadiazine has a higher and more prolonged blood concentration than the others in this group.

8. Sulfadiazine is superior in its effectiveness against the streptococcus, the pneumococcus, Friedländer's bacillus, and the *E. coli* group. It is the equal but not superior in its therapeutic activity on the staphylococcus but is the choice because of lowered toxicity.

9. Sulfaguanidine has effective bactericidal action on the coliform organisms.

10. Intravenous anesthesia containing barbiturates administered during sulfonamide drug therapy is contraindicated.

CHRONIC PYELONEPHRITIS

REED M. NESBIT, M.D., and KYRIL B. CONGER, M.D., Ann Arbor, Michigan

PYELONEPHRITIS is the most common disease of the kidney. In its acute stage it is ordinarily easy to recognize and may be successfully treated in most instances. Once the disease becomes chronic, however, the diagnosis is far less obvious and treatment is of dubious value in many cases. The symptoms of chronic pyelonephritis are highly variable, some patients having a minimum of subjective disturbance, while others may suffer renal, bladder, or vascular symptoms that are completely incapacitating. Likewise, the pathology may range from the involvement of only small areas of the kidney to almost complete destruction of both organs by scar tissue and inflammatory processes. There is sometimes complete lack of correlation between the symptoms and the severity of the pathologic process, and the patient who is unaware of any urologic abnormality may be in a terminal phase of the disease. On the other hand, a majority of patients return again and again for treatment of distressing symptoms that have a tendency to recur despite every type of therapy.

Clinical data on 172 cases of chronic pyelonephritis seen during the last ten years have been reviewed and constitute the basis for this report. In 80 per cent of these the diagnosis was verified by characteristic pyelographic changes or pathologic examination. The remaining 20 per cent had normal pyelograms, the diagnosis being established on the basis of known chronic infection of the upper part of the urinary tract proved by ureteral catheterization. Cases of renal infection obviously secondary to calculus disease or hydronephrosis were excluded from this series because our main interest was in the disease as it affects a previously normal kidney.

Age and Sex Incidence

It is generally recognized that pyelonephritis is more common among women than men. Caulk⁵ found a proportion of 684 women to 225 men and estimated that in children girls predominated 3 to 1, that in adults women predominated 2 to 1, and that in the fifth to eighth decades the ratio was about even. In

our series, 62 per cent occurred in women and 38 per cent in men. As seen in Fig. 1, it is most common in women from the second to fifth decades or during the period of active sexual life. In men it reached its peak in the fourth decade. There were more cases in men than in women after the age of 60. One hundred and thirty-nine (81 per cent) had bilateral lesions. Of the remaining unilateral lesions, 22 (12.6 per cent) were of the right kidney and 11 (6.3 per cent) were of the left kidney.

Etiology and Predisposing Causes

Among the 107 women (Table 1), 36 cases gave a history suggesting etiologic or predisposing factors. Eighteen patients previously had acute renal infections during pregnancy, and the onset of their symptomatology corresponded roughly with that event. Prather⁷ has recently shown that 23 per cent of patients with pyelonephritis of pregnancy are apt to have a recurrence with subsequent gestation, an incidence of about ten times that normally occurring with pregnancies as a whole and illustrating the tendency of this disease to become chronic. Eight presented histories of focal infections which coincided

DISTRIBUTION BY AGE AND SEX

FIG. 1. Age and sex incidence of chronic pyelonephritis.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

From the Department of Surgery, University of Michigan, Ann Arbor, Michigan.

FIG. 2. W. W. died of renal failure after eighteen years' history of chronic bilateral pyelonephritis. Photomicrograph shows interstitial fibrosis, round-cell infiltration, and tubular dilatation. Note the fibrosis of glomerular capsules and tufts, with almost complete obliteration of some glomeruli by scarring, and hypertrophy of unaffected glomeruli.

with the development of the disease. These included 2 cases of cervicitis, 2 cases of pelvic inflammatory disease, 1 case of erysipelas, 1 case of deep cervical abscess, 1 case of general cachexia due to carcinomatosis, and 1 case of acute lower neisserian infection. Four cases followed instrumentation, 2 of these following prolonged indwelling catheterization, 1 following a transurethral resection of a bladder tumor, and 1 following a criminal abortion—method unknown. Three were associated with definite congenital anomalies of the kidneys. There was 1 case each following pyelolithotomy, trauma, and infection of the lower part of the urinary tract following defloration.

Among the men, 37 gave histories suggesting etiologic factors. Twenty were ascribed to previously existing genital tract infections. These included a variety of findings such as strictures, prostatitis, seminal vesiculitis, and urethritis, both of specific and non-specific types. We believe this illustrates that occasionally these supposedly benign infections may be foci for important ascending infections, as has been pointed out by Von Lackum and others. Nine cases were attributed to prostatism. Three cases followed other foci (1, bronchopneumonia; 1, tonsillitis; 1, multiple bronchiectatic abscesses). Three cases resulted from indwelling catheterization following abdominal surgery. Two cases followed previous calculus disease.

It is interesting to note that 42.5 per cent

of our cases presented some etiologic factor to which the disease might be attributed. It is possible that adequate and intensive treatment of the presumed predisposing causes might have prevented the development of chronic pyelonephritis in many of the cases.

In this connection it is interesting to consider the work of Wharton, Gray, and Guild,¹² who made a follow-up study of 30 patients, all women, who previously had had acute infections of the upper part of the urinary tract before the age of 5. Nine had had only one attack of "pyelitis" and, of these, 6 showed an abnormal urinary tract by urinalysis, pyelogram, or function study. Twenty-one patients had had two or more attacks and, of these, 11 showed abnormalities of the urinary tract by the same criteria.

Pathology

The best description of pyelonephritis with regard to correlation with its clinical features is that of Weiss and Parker¹¹ in which the disease is classified into four groups according to its various stages: (1) acute pyelonephritis ("pyelitis"), (2) active chronic pyelonephritis, (3) healed diffuse pyelonephritis, and (4) healed pyelonephritis with recurrence. The term "healed" is probably misleading, since, although the activity of the infection is quiescent, the destruction of kidney function by parenchymatous contracture may be advancing.

The acute stage of pyelonephritis is not often observed pathologically because nearly all patients recover. Those dying from acute ascending infections usually have widespread lesions of the kidney with abscesses and marked necrosis (according to a study by Kennedy⁶).

In chronic pyelonephritis (Fig. 2) there is, first, formation of inflammatory tissue in the interstitial structure of the kidney with atrophy of the tubules. The process then extends to the glomeruli, causing fibrosis of the capsule and glomerular tuft. The basement membrane may become thickened. Later, the tubules become dilated and filled with colloid or hyalinized secretions, due to retention at the corticomedullary junction caused by inflammation and fibrosis, and the glomeruli undergo further destruction. Finally, the whole area of the kidney in which the process is occurring may become a mass of inflammatory tissue with only faint remains of normal architecture. These changes were first described by Staemmler and Dopheide.¹⁰ This process may be unilateral or bilateral and

FIG. 3(A).

FIG. 3(B).

FIGS. 3(A) and 3(B). A. C., aged 48, was first seen here in February, 1939. There was marked impairment of renal function at that time; the blood pressure was 230/150. Diagnosis: chronic pyelonephritis.

(A) Pyelogram taken four years previously (February 7, 1935) at another hospital shows narrowing of infundibula, characteristic of chronic pyelonephritic contraction.

(B) Pyelogram made here on March 25, 1939, shows nonfilling of calices in both kidneys with obvious adequate injection of contrast medium.

may involve the whole kidney or be confined to restricted areas. Different parts of the kidney may show different stages of the disease (Putschar⁸). There may be compensatory hyperplasia of the uninvolved glomeruli.

The classification of Weiss and Parker¹¹ affords a satisfactory pathologic explanation of the clinical features of the disease. In chronic active pyelonephritis the infection is active and pyuria and bacteriuria may persist for a long time, giving rise to definite urologic symptoms. It may be accompanied by vascular changes in the kidney.

In "healed" diffuse pyelonephritis the patient is in a noninfectious stage. This probably represents the pathologic picture in a majority of cases of acute pyelonephritis which subside completely without any subsequent clinical significance and is attested by discovery of scars during postmortem examination of patients who died of other causes.

On the other hand, as the authors point out, in a number of patients arterial changes may develop. There is lymphoid infiltration of the

interstitial tissue and pelvis, and there are colloid casts in the tubules. The tissue response initiated by active infection may advance after the infection has subsided, producing a progressive cicatrization, which may involve normal functioning tissue.

By "healed pyelonephritis with recurrence" the authors designate the stage in which active infection recurs and is superimposed upon the preceding stage. Here again, urinary symptoms with bacilluria and pyuria may become prominent.

Striking changes in the gross renal architecture may result from chronic pyelonephritis, with the shutting off of an entire calix or calices from communication with the pelvis by contraction of scar tissue in the region of the infundibula. It may even be difficult to diagnose the disease by pyelography in such a far-advanced stage because of the cutting off of the caliceal components from the pelvis, which remains the only part of the kidney filled with contrast medium. Such a case was previously studied here. Pyelograms were done four years previously at another hospital and

Fig. 3(C).

Fig. 3(D).

FIGS. 3(C) and 3(D). Photograph of kidneys removed at autopsy two months later demonstrates complete stenosis of all infundibula right kidney and all upper infundibula of left kidney. Infundibulum of inferior major calix still communicates with pelvis.

TABLE 2.—INITIAL SYMPTOMS IN CHRONIC PYELONEPHRITIS

Type of Onset (Symptoms of Which Patients Were First Aware)	No. of Cases	Percentage
1. Cystitis Of these, 43, or 24%, also had costovertebral pain as initial symptoms	105	61
2. Costovertebral pain	30	17
3. Sepsis	8	4.6
4. Insidious	29	16

showed narrowing of the infundibula as in Fig. 3(A). The patient was seen here in a pre-terminal stage, and the pyelograms made are shown in Fig. 3(B). This patient later died at the Eloise Infirmary, and the autopsy findings were published by Siler.⁹ Reproduction of the early pyelograms and photographs of the kidneys is by permission of the author (Figs. 3(C) and 3(D)).

FIG. 4. V. J., aged 37, with a two-year history of chronic pyelonephritis and a blood pressure of 242/138, died of chronic bilateral pyelonephritis, confirmed by autopsy. Note irregular dilatation of both ureters with filling defects in left resulting from far-advanced ureteritis cystica. Calices in both kidneys show marked constriction from gross cicatricial contraction of parenchyma.

The Clinical Picture of Pyelonephritis

(1) *Initial Symptoms.*—In our series the duration of symptoms prior to diagnosis varied from three months to twenty years, with an average of five years. Sixty-one per cent had cystitis as an initial symptom and, of these, almost one-half had accompanying flank pain, either unilateral or bilateral. Costovertebral pain alone was present in 17 per cent at the onset (Table 2), and 4.6 per cent of the cases were initiated by sepsis alone without any other urologic symptoms. Sixteen per cent had an entirely insidious onset. As far as prevention or cure is concerned, it is obvious that 84 per cent of the patients could reasonably have been diagnosed at an earlier stage of the disease and might have benefited by earlier treatment.

(2) *Infecting Organisms.*—Most writers have agreed that the colon bacillus is the most frequent invader in chronic pyelonephritis, although a great variety of bacteria have been found. Keyes stated that when urine was obtained directly from the renal pelves a Bacil-

TABLE 3.—PERCENTAGE AND DEGREE OF PYELOGRAPHIC CHANGES

Pyelograms		
No pyelograms (autopsy diagnoses)	13	
Pyelograms	159	
Of 159 pyelograms done	No. of Cases	Per-centage
No changes	36	22.6
Minimal changes	87	54.7
Moderate changes	24	15
Marked changes	12	7.5

of these showed characteristic pyelographic changes at a later stage of the disease.

The ureter may be irregularly dilated throughout due to chronic inflammation with scarring of the wall. Rare cases of ureteral stricture with hydroureter have been described. The outlines of the kidneys themselves may show a definite decrease in size of organs due to progressive destruction by inflammation and scar tissue. In a like manner, this scar-tissue contraction distorts the pyelogram in various ways, causing dilatation of some parts of the kidney and constriction in others. The site most predisposed to constriction is the infundibulum. This process may go on to the point where a calix is completely shut off from the pelvis and is lost from the pyelogram, or various degrees of dilatation, including hydrocalicosis, may develop (Figs. 3(A) and 3(B)). The outline of the calices may become irregular and in far-advanced cases may be difficult to distinguish from tuberculosis. Some characteristic pyelograms in far-advanced disease are shown (Figs. 4 and 5).

In our series of 172 cases, 159 pyelograms were made. These were normal in 22.6 per cent; 54.7 per cent showed minimal changes; 15 per cent, moderate changes; and 7.5 per cent, marked changes (Table 3). Of what prognostic value are the pyelograms? A comparison of morbidity and mortality was made between those patients showing minimal or no pyelographic changes and those showing moderate and marked changes. During the period of observation, deaths from the disease occurred in 4.2 per cent of the former and 15.1 per cent of the latter (Fig. 6). Thus, we can say definitely that degree of pyelographic change gives us some index as to the prognosis and future course of the patient.

(4) *Renal Function.*—In 72 cases, function studies were done, consisting of a blood non-protein nitrogen or one or more of the following tests: a urea clearance, phenolsulphonphthalein, excretion, or concentration. Non-protein nitrogen estimations alone were not

FIG. 5. A. B. had a unilateral chronic pyelonephritis with hypertension cured by nephrectomy. (Case previously reported.) Diagnosis was confirmed by pathologic examination. Dilation of major and minor calices in this situation has not resulted from obstruction, since pelvis is of normal size. Thinning out of cortex from cicatricial contracture is in this instance solely responsible for the widening of calices.

lus coli infection was responsible in about 90 per cent of the cases. Cabot^{3,4} estimated the percentage as 70.4 and stated that it was even higher than this in women alone.

In most of our cases cultures were not carried out, reliance being placed on stained catheterized specimens in women and stained fresh second-glass specimens in men whenever ureteral catheterization was not done. By this method we found that 51 per cent of the patients showed bacilli; 21 per cent, cocci; and 15 per cent, a mixture of the two. Twelve per cent of the patients showed no organisms by stain whatsoever, although definite pyelographic changes were present.

(3) *Pyelographic Changes.*—The x-ray changes in chronic pyelonephritis are characteristic when present and, of course, depend upon gross structural abnormality of the kidney. That chronic pyelonephritis may be present before these changes occur is illustrated by the fact that 22 per cent of our cases having x-rays showed normal pyelograms at the time the diagnosis was established. Some

PYELOGRAPHIC CHANGES

TABLE 4.—PERCENTAGE AND DEGREE OF RENAL FUNCTION INVOLVEMENT

Function	No. of Cases	Per-centage
Number cases in which function tests done	72	
No impairment	18	25
Minimal impairment	17	23.6
Moderate impairment	19	26.4
Marked impairment	18	25

considered adequate tests of renal function unless they were definitely elevated, in which case marked impairment of the renal function was presumed to have occurred. Cases without elevation of the nonprotein nitrogen but impairment of phenolsulfonphthalein, excretion, urea clearance, or concentrating ability were classified as having minimal or moderate impairment, according to the degree noted. Seventy-five per cent of all cases on whom function tests were done showed some impairment. Twenty-three and six-tenths per cent showed minimal impairment; 26.4 per cent, moderate impairment; and 25 per cent, marked impairment (Table 4).

Studies of renal function provided the most accurate prognostic index available in this group of patients (Fig. 7). In those cases showing no impairment of renal function there was a high incidence of clinical improvement and no deaths during the period of observation and treatment. With progressive decrease in renal function a less favorable response to treatment, together with increased mortality rate, was observed.

(5) *Hypertension*.—Within the past few years the relationship of pyelonephritis, both unilateral and bilateral, to hypertension has been studied with particular interest. It is now well established that pyelonephritis, as well as other types of kidney disease, can produce hypertension. Weiss and Parker¹¹ estimated that pyelonephritis was responsible for 15 to 20 per cent of all cases of malignant hypertension. Braasch and Jacobson,² in reviewing 180 cases of bilateral chronic pyelonephritis of all ages, found that 47, or 26 per cent, had accompanying hypertension. However, in a control group of all ages the incidence of hypertension was 20 per cent. By placing the patients in two groups, the incidence of hypertension in patients under 50 was found to be almost twice that found in the control group; whereas, in those over 50 the incidence was approximately the same. The authors found that in chronic pyelonephritis the incidence of hypertension increased with (1) the duration of symptoms and (2) the severity of pyelographic changes.

FIG. 6. Prognostic value of degree of pyelographic changes.

FIG. 7. Prognostic value of renal function studies.

In our series of 172 cases we found the incidence of hypertension for all age groups to be 34 per cent, an increase of 14 per cent over the normal expectancy rather than 6 per cent as found by Braasch. Since the average age of the group at Mayo Clinic and our group was nearly the same (Braasch's, about 42 years; ours, 38.6 years), our figures are significantly higher. Like Braasch, we have found the incidence of hypertension in patients with a long duration of symptoms to be higher (about 13 per cent) than in those with a relatively short history (under a year) in which the incidence was 20 per cent or approximately the same as those of Braasch's control group. Hence, we may conclude from our studies that hypertension rarely is brought on by pyelonephritis of only a year's duration.

Hypertension was found in 34 per cent of our cases. In 12 per cent the pressure was over 140/90. In 10 per cent it was over 160/110, while in 11 per cent it was over 200/140. The criteria for arranging the patients in these groups was the elevation of either systolic or diastolic readings above those mentioned (Table 5).

That the degree of hypertension is of prognostic significance is shown by the fact that among the patients adequately followed in these three groups there were mortality rates from the disease of 7.6 per cent, 18 per cent, and 54 per cent, respectively. Likewise, of the 17 patients in our entire series dying of pyelonephritis, 11 had hypertension of at least two months' duration preceding their demise. An additional 2 developed terminal hypertension.

(6) *Progress of Disease.*—Chronic pyelonephritis may undergo long periods of remission from its active infectious stages, as was mentioned in the discussion of its pathology. We have been impressed by the fact that many infections apparently remain quiescent over a period of years, while others may advance rapidly and terminate fatally within a short time.

In this study, all cases were divided into groups according to the length of duration of their symptomatology. This was relied upon as an estimate of the length of the disease prior to the patient's study at the hospital. It is, of course, entirely possible that in many cases estimates arrived at by this method were wrong because of the relatively insidious onset of disease in some cases and because of the tendency for many patients to overlook slight episodes of acute renal infections occurring

FIG. 8. Progression of chronic pyelonephritis according to length of duration of symptoms.

TABLE 5.—PERCENTAGE AND DEGREE OF HYPERTENSION

	No. of Cases	Percentage

in the distant past and which seemed unrelated to their present difficulties.

In 160 cases with adequate histories for this estimation, 12.5 per cent (Group 1) had symptoms for less than three months prior to our studies. Fifteen and six-tenths per cent had symptoms from three to eleven months (Group 2). Thirty-three and seven-tenths per cent had symptoms for one to five years (Group 3), while 38 per cent had symptoms over five years. The average duration of preceding symptomatology was four years and nine months.

In correlating the apparent duration of the disease with the clinical evidences of its severity as shown by pyelograms, function studies, and hypertension, it can be seen that there is a tendency toward gradual progression of all those factors (Fig. 8). The percentage of moderate and marked pyelographic changes was slightly higher after a year's duration of symptoms, while there was a 13-per cent increase in the incidence of hypertension after this period. The percentage of renal function impairment remained about the same until five years of symptoms had elapsed; then it increased from an average of 25 per cent to 40

TABLE 6.—PROGNOSIS

Cured symptomatically	3	2.3

* Thirteen died, autopsy confirmed pyelonephritis as cause of death. Four died, undoubtedly of pyelonephritis without autopsy.

per cent. It seems apparent from this study that a gradual progression of the disease, which, however, is not too striking, occurs with its duration. It must be borne in mind, however, that there are cases where the disease may exist for many years with little effect upon renal function, pyelograms, or blood pressure, while the opposite may be true of cases with only the briefest duration of symptoms, in which the whole course of the disease is short and fulminating.

(7) *Prognosis*.—In 1927 Braasch and Cathcart¹ stated that one-third of all patients with chronic pyelonephritis recovered, another third were remarkably improved, and one-third were not helped by treatment. In our series, 130 of 172 cases were adequately followed to provide information of value regarding prognosis. There were 25 deaths in this group, of which 17 were undoubtedly attributable to chronic pyelonephritis. Of these, 13 were autopsied and the diagnosis was confirmed. Deaths occurred on an average of five years and ten months following the onset of symptoms. Six patients, or 4.6 per cent, became definitely worse while under treatment. Thirty-seven per cent showed no great change for better or worse; in the majority of cases they had periods of remission and exacerbation of symptoms of about the same intensity as had existed prior to treatment. Thirty-four and six-tenths per cent of our patients appeared to be improved in general health and symptoms. Only 3 patients (2.3 per cent) became asymptomatic and showed a consistently negative urine on repeated examinations (Table 6). Except for our lower incidence of cures, these figures correspond pretty well with those of Braasch and Cathcart.¹

Treatment

Nearly all the patients who stayed long enough for adequate therapy received a number of varying types of treatment currently in

vogue at the time of hospitalization. No outstanding cures were achieved by any particular drugs, except that in the later cases treatment with mandelic acid and sulfanilamide compounds gave longer periods of remission from infections than any of the older medications. With the initial use of these drugs, several spectacular remissions occurred in cases where the urine had been grossly infected over long periods of time; in most of the latter, abandonment of the drug was followed by return of the infection sooner or later. This study offers no new ideas on therapy once the disease has been established.

It cannot be expected that the structural and functional changes of long-standing pyelonephritis can be reversed, even though bacteriologic arrest is effected. It is rather in the prophylaxis of chronic pyelonephritis that the physician has the opportunity of rendering the greatest benefit to patients. Since most chronic pyelonephritis starts as an acute disease, usually with clear-cut symptoms and ease of diagnosis, all patients with acute pyelonephritis should be treated conscientiously not only until the symptoms have disappeared but until the urine has been bacteria-free on repeated occasions. The attainment of this is sometimes difficult. The patient, relieved of distressing symptoms and sepsis, although still having infected urine, feels that he is well and naturally loses interest in further treatment. Unless informed at this time by a conscientious physician, he may remain entirely unaware that he still harbors infection and that he is a potential candidate for the development of chronic pyelonephritis unless his urine becomes bacteria-free. Modern chemotherapeutic agents are the most effective for this purpose. At the present time the best drugs are probably mandelic acid and the sulfanilamide group.

FOLLOW-UP STUDY OF SO-CALLED PYELITIS IN CHILDREN

EDGAR SLOTKIN, M.D., Buffalo, New York

THIS paper presents the results of a follow-up study of 45 cases of so-called pyelitis or, better termed, urinary infection in children.

All the cases were seen from two months to nine years after the original infection, with the average time as just over two years. A history and physical examination were made. In addition, a urine culture was carefully obtained under special precautions: first, the vulva was washed with green soap and water; second, a mercurial antiseptic was used to paint the urethral meatus; finally, small steel catheters, instead of rubber ones, were passed in order to avoid touching and contacting the vaginal wall.

There were 41 girls and 4 boys, ranging in age from 3 months to 15 years—the average being 10 years. All but 3 had been previously hospitalized and treated for urinary infection. On return, most of the patients had no complaints but, on inquiry, the following symptoms were elicited: (1) occasional frequency and nocturia, 8 cases; (2) repeated attacks of pyelitis (by history), 4 cases; (3) underweight, 2 cases; (4) pain in the back, 1 case; (5) pain in the abdomen, 1 case; (6) enuresis, 1 case; and (7) hematuria, 1 case.

Twenty-six cases had intravenous or retrograde pyelography or both; 17 had intravenous and retrograde; 8 had intravenous alone; and 1 had retrograde alone. Pyelography revealed the following lesions: (1) obstruction of ureteral-pelvic junction (aberrant vessels), 3 cases; (2) stricture of the ureter, 3 cases; (3) double pelvis of the kidney, 3 cases; (4) congenital absence of right kidney with infected hydronephrosis of the left, 1 case; (5) bilateral hydronephrosis (narrowing at vesical-ureteral junction on the left side; stricture of pelvic-ureteral junction on the other side), 1 case; (6) bilateral hydronephrosis, hydroureter with one double ureter, 1 case; and (7) fibrosis of vesical neck (bilateral hydronephrosis), 1 case hydroureter with one double ureter.

Twelve cases out of 45 that reported back for examination, or over 26 per cent, showed some abnormality.

Wharton, Gray, and Guild¹ studied 30

From the Buffalo Children's and Buffalo General hospitals.

girls nine and three-fifths years after their acute attack of pyelitis and found that 17 or 57 per cent had abnormalities by intravenous pyelography. I believe there exists a higher percentage of urinary tract pathology in children having so-called pyelitis than we formerly suspected. I should like to present a summary of a few of our interesting cases.

Case Reports

Case 1.—A girl, aged 10, entered the hospital complaining of nausea and vomiting, right lower quadrant pain, chills, and fever. She had nocturia once a night with no other urinary symptoms. She had previously had a similar attack that had subsided in a few days. On examination the urine was loaded with pus cells, *Bacillus coli* and *Streptococcus fecalis* were cultured. The residual urine was 250 cc. The cystoscopic examination revealed a fibrosis of the vesical neck and a bilateral hydronephrosis and hydroureter, which was more marked on the left side. A cystogram showed a reflux up the left ureter and kidney pelvis (a large destroyed left kidney). A resection of the vesical neck was done by Dr. Parmenter. Now, the patient has no residual urine, no pus cells in the urine, but *B. coli* can still be cultured. The right hydronephrosis has disappeared; the left reflux is still present. This child has gained about 20 pounds since the operation and has no complaints.

Case 2.—Another girl, aged 5, had numerous attacks of left-sided lumbar pain, nausea, vomiting, chills and fever, and persistent enuresis. A left pyelogram showed an obstruction at the left pelvic-ureteral junction. An attempt was made to relieve this by removing adhesions and eliminating an aberrant vessel. Since the operation the patient has had four attacks similar to those first mentioned. On re-examination the left kidney was functionless. A nephrectomy was performed and the patient has been fine since that time.

Case 3.—Another case, similar to the above, was that of a boy, aged 8, with recurrent attacks of enuresis and colicky left lumbar pain. The urine showed *B. coli* and pus cells, and on cystoscopic examination a left functionless hydronephrosis was found. A nephrectomy was performed which revealed an aberrant vessel at the pelvic-ureteral junction. The patient has been fine since the operation.

Case 4.—A girl, aged 6 months, entered the hospital because of fever and refusal to take food. Pus cells were found in the urine. She was not seen for two and a half years following the first admission, when intravenous and retrograde pyelography showed a large left infected hydro-

TABLE 1.—SUMMARY OF URINE CULTURES—45 CASES

Original Infection		Follow-up Cultures	
<i>B. coli</i> , <i>Str. fecalis</i>	11	Sterile, 24	Positive, 21
<i>B. coli</i>	8	<i>Str. fecalis</i> , <i>Staph. aureus</i>	6
<i>Str. fecalis</i>	4	<i>Str. fecalis</i>	5
<i>Staph. aureus</i>	5	<i>B. coli</i>	3
<i>B. aerogenes</i> , <i>Str. fecalis</i>	3	<i>Str. fecalis</i> , <i>B. proteus</i>	3
<i>B. morgani</i>	2	<i>Str. fecalis</i> , <i>B. coli</i> , <i>B. aerogenes</i>	1
<i>Str. fecalis</i> , <i>Staph. aureus</i>	1	<i>B. coli</i> , <i>Str. fecalis</i>	1
<i>B. coli</i> , <i>B. aerogenes</i> , <i>B. morgani</i> , <i>Staph. aureus</i>	1	<i>B. coli</i> , <i>B. aerogenes</i>	1
<i>Str. fecalis</i> , <i>B. aerogenes</i> , <i>B. coli</i>	1	<i>Staph. aureus</i> , <i>B. subtilis</i>	1
Culture not taken	9		
Prevalence of Organisms		Prevalence of Organisms	
<i>B. coli</i>	21	<i>Str. fecalis</i>	14
<i>Str. fecalis</i>	20	<i>B. coli</i>	6
<i>Staph. aureus</i>	7	<i>Staph. aureus</i>	7
<i>B. aerogenes</i>	5	<i>B. proteus</i>	3
<i>B. morgani</i>	3	<i>B. aerogenes</i>	2

All of these cases of original infection had pus cells in the urine and clinical signs of infection.

In this follow-up series 8 cases had pus cells in the urine. Nine had some organisms that were present in original infection.

TABLE 2.—SUMMARY OF URINE CULTURES—NO HISTORY OF FINDINGS OF UROLOGIC DISEASE

Female Children (2 mo.—15 yr.)		Women (16-72 yr.)	
<i>Staph. aureus</i>	7	<i>Str. fecalis</i>	7

		Anaerobic gram-negative bacillus, <i>B. subtilis</i>	1
		<i>B. subtilis</i>	1
Prevalence of Organisms		Prevalence of Organisms	
<i>B. coli</i>	10	Anaerobic streptococcus	9
<i>Staph. aureus</i>	8	<i>Str. fecalis</i>	9
<i>Str. fecalis</i>	7	<i>Staph. aureus</i>	4
<i>B. aerogenes</i>	2	In 26 positive cultures, 18 had a few, or rare, white blood cells. Nine had organisms on direct smear.	

nephrosis and no right kidney or kidney shadow was found. This child is now 8 years old. The urine is loaded with pus cells, and the culture shows *B. coli* and *Str. fecalis*. With any of the sulfanilamide group of drugs the urine becomes crystal clear, and as soon as they are stopped pus cells and bacteria return.

Case 5.—A boy, aged 6, had had nausea, vomiting, and right lower quadrant pain. He entered the hospital and naturally had an appendectomy performed. This did not relieve the complaints. The urine showed varying amounts of pus cells at different times and *Str. fecalis*. Cystoscopic examination showed a stricture at the left vesical-ureteral junction and a stricture of the right ureter at the pelvic-ureteral junction. Following cystoscopy the patient has had no pains and urine has been clear.

Case 6.—A boy, aged 10, was practicing diving and took a "belly-flop." Following this he had severe left upper quadrant pain, emesis, frequency of urination, and a brown colored urine. This persisted and the boy was brought to the hospital. The urine showed many red and white blood cells. Culture showed *Staphylococcus aureus* hemolyticus. No function was obtained from the left kidney by intravenous pyelography, and it was impossible to catheterize the left ureter because of a stricture at the vesical-ureteral junction. Surgery revealed a large hydro-

nephrotic sac caused by an aberrant vessel at the pelvic-ureteral junction.

Case 7.—A girl, aged 3 months, was seen because of frequency of stool and a distended abdomen. Five hundred cubic centimeters of infected urine was obtained by catheterization. The culture showed *B. coli*, *Bacillus aerogenes* and *Str. fecalis*. Cystogram showed a large bladder displaced to the left. Cystoscopic examination showed a bilateral hydronephrosis with a double pelvis and ureter on the left side. The child, when last seen, was gaining weight and looked fine, but her urine was loaded with pus cells. We were unable to persuade the parents to bring in this child for further study and treatment.

In 45 cases of original infection, the follow-up cultures revealed 24 sterile cultures and 21 positive. The results are listed in Table 1.

This bacteriologic study seemed to be an interesting finding because it disclosed such a high percentage of cases with positive cultures. Did this mean that these patients still harbored pathogenic organisms? Did this mean that these cases should still be treated? Were these organisms the normal bacterial flora of the female urethra and bladder?

In 1937 Wharton, Gray, and Guild⁴ studied

30 women who had pyelitis in infancy. I previously referred to this work. Their series showed that 15, or 50 per cent, had positive cultures; the frequency of the organisms was as follows: *B. coli*, 9; *Staphylococci*, 4; *Dysentery, bacillus*, 1; *Shigalla Dispar Bacillus*, 1; and *Alpha-streptococci*, 1.

The percentage of positive cultures and the organisms found, compare with my group of 45 cases except for the *Str. fecalis*.

The high percentage of positive cultures raised the question as to what culture, if any, would be obtained on supposedly normal women. Urine cultures were taken on 100 women who had no history or findings of any urologic disease. In the group of female children between the ages of 2 months and 15 years, 23 sterile cultures and 27 positive cultures were obtained. In the group of women between the ages of 16 and 72 years, there were 24 sterile cultures and 26 positive cultures. In this group of 26 positive cultures, 18 had a few, or rare, white blood cells. Nine had organisms on direct smear. A summary of urine cultures done on 100 cases is shown in Table 2.

We find that the prevalent organisms are about the same as those we obtained in our follow-up series, appearing in the same frequency and percentage as in those children who had previous infection. In the adult series again we have the same percentage of positive cultures, but the organisms are somewhat different than appear in the children, since the anaerobic streptococcus is prevalent and the *B. coli* appears in only 2 cases in this group.

Schulte² reported in 1939 that nearly all the patients, both men and women, on whom bladder urine was obtained for culture through the cystoscope had positive cultures from the bladder and negative cultures from the kidney pelvis. Also a Gram's stain of the urinary sediment failed to show any organisms. He found that the organisms occurred in the same frequency as they did in the male urethra appearing in this order: micrococcus, diphtheroids, *Str. fecalis*, alpha-streptococcus, gamma-streptococcus, *Staphylococcus albus*, *Escherichia coli*, Aerobacter aerogenes, and pseudomonas. He did not mention the number of cases used and the number of times each organism appeared, and he did not give the percentage of male and female patients. In my normal series we did not culture the micrococcus and cultured the diphtheroids only once. Leishman³ cultured the bladder urine from 50 healthy women and obtained

B. coli four times; no other organisms were reported.

Conclusion

1. Urinary infection in children should not be taken casually, since there exists a higher percentage of abnormalities than is ordinarily suspected. An attempt at complete urologic diagnosis should be made. Early care and treatment may prevent further infections and complications.

2. A normal bacterial flora of the female urethra and bladder neck exists. There is a difference between the flora of adults and children.

. . .

I wish to thank Dr. F. J. Parmenter, chief of the Urologic Department of the Buffalo Children's and Buffalo General hospitals; Dr. Erwin Neter and Dr. Ernest Witebsky for bacteriologic studies; Dr. Ralph De Graf for radiographic studies; and Dr. Samuel Sanes.

Discussion of Symposium

Dr. W. W. Scott, Rochester, New York—Drs. Borst, Nesbit and Conger, and Slotkin are to be congratulated upon their excellent papers. Dr. Borst has told us in a clear, concise manner the story of the sulfonamides, stressing especially their relative effectiveness in the treatment of infections of the upper part of the urinary tract. In the order in which these drugs have been introduced to the medical profession, we have tried them in the treatment of infections of the upper part of the urinary tract. In our experience with the sulfonamides in common use today, sulfathiazole has proved to be the most satisfactory. From the very beginning our fear of the complications arising from the presence of too much of the insoluble acetyl sulfathiazole in the urine prompted us to use relatively small doses of the drug, giving it four or five times in twenty-four hours. We were greatly pleased with the clinical results and the relative absence of toxic symptoms. Helmholtz and others have recently reported results confirming our personal observations. The splendid clinical results we have observed in a limited number of cases treated by sulfadiazine, may well be due to its high percentage of excretion by the kidneys, its low toxicity, its marked solubility in the urine, and its high bactericidal properties. However, in our enthusiasm for the

sulfonamides let us not forget the value of proper drainage, the elimination of foci of infection, and the correction of improper habits of body hygiene, in the treatment of infections of the upper part of the urinary tract.

Dr. Nesbit has presented the subject of chronic pyelonephritis in a complete and instructive manner. As emphasized by him, the most successful treatment of chronic pyelonephritis is to be found in the field of preventive medicine. The cooperative patient who receives intelligent, thorough treatment during the acute or subacute stage of the disease seldom develops a chronic renal infection. Because of the varying reactions of the different species and types of bacteria to urinary antiseptics and other therapeutic measures, I believe it is important that the urologist and the internist work in close cooperation with the bacteriologist in the treatment of infectious diseases of the kidneys. In my opinion, where infections persist or recur, retrograde studies are of considerable more diagnostic, as well as therapeutic, value than intravenous pyelography.

Dr. Slotkin's presentation ties in nicely with the paper by Drs. Nesbit and Conger. The role of structural abnormalities of the genitourinary tract in persistent and recurrent renal infections is clearly demonstrated. The need of early intravenous or retrograde studies in such cases cannot be too frequently and too strongly emphasized.

I am at a loss to explain the high incidence of *Str. fecalis* infections in Dr. Slotkin's series of cases. In our experience and the experience of other writers on the subject, this organism has not been found so frequently. Fortunately, the *Str. fecalis* rarely attains the resistance and pathogenicity of some of the other organisms frequently found in the urinary tract. It is not clear in my mind as to whether or not the patients in his series were all proved to have infections of the upper part of the urinary tract. The persistence of a bladder infection is more suggestive of involvement of the upper part of the urinary tract than the mere presence of the organism in the bladder urine over a short period of time. I believe Dr. Slotkin's point concerning the existence of a normal flora in the female urethra and bladder is well taken.

Dr. George E. Slotkin, *Buffalo, New York*—One who has the privilege of hearing a symposium on a subject of such importance and magnitude—on the role, the prevalence, and the disastrous results from urinary infections—can only be grateful that the door of enlightenment has been opened still further to enable us to attack this subject more clearly.

We who have not only the privilege, therefore, in addition, to discuss the same are handicapped by an inability to detract one iota from the perfect manner in which the subject has been covered. It therefore leaves one with the alter-

native of adding a point or two, in summary of the three papers presented. We have heard that symptom-free individuals, whether they are children or adults, harbor offensive organisms, quiescent it is true but ready under the slightest provocation to become activated and create the symptoms of serious infection of the upper part of the renal tract, and when this condition occurs we have learned of the chemotherapeutic agents to defend this condition against the organism that may be determined.

The important lesson to be derived, I believe, from these three papers may be crystallized into a few important facts: first, that pyelonephritis is a serious disease and can be the cause of hypertension in from 20 to 34 per cent of the cases in the creation of a permanent renal ischemia through fibrosis of the glomeruli by scarification, atrophy of the tubules, and fibrous deposition in the terminal vessels of the kidney; and second, that this condition may follow the simplest of procedures—a simple catheterization with subsequent activation of dormant organisms and the development of a profound infection or the presence of a low-grade seminal vesiculitis, prostatitis, or stricture. It is not sufficient, therefore, for the physician who sees the urinary infection first to minimize the seriousness of this condition by discharging the patient when the urine is pus-free. Successive cultures must be taken until this urine is bacteria-free, as Dr. Edgar Slotkin has shown. It is also important to determine the response of the condition to therapy after the organism is disclosed, for I am certain that we have all seen urinary infections with concurrent types of organisms which are antagonistic in their response to any one preparation and have been overgrown by the predominating infection.

Therefore, may I suggest in the final analysis that the urologist has an important mission toward the patient and the practitioner who usually sees this patient first to impress upon them the importance that no case of urinary infection be discharged as cured until they are bacteria-free, that successive cultures be made of urine where desired response does not occur to medication, and that in every instance of urinary infection which does not respond to proper therapy the entire urinary tract must be investigated to discount the possibility of a low-grade pyelonephritis persisting for years with the ultimate possible development of the pathologic changes therefrom which create chronic invalidism.

Dr. Albert M. Crance, *Geneva, New York*—All three papers in this symposium have been excellent—the kind of papers we go home and think about and anxiously await their appearance in the *Journal*, so that we may enjoy going over them more carefully.

The first paper by Dr. Borst is a splendid review of the comparative values of the various sulfonamides. I agree with him 100 per cent

regarding sulfathiazole—that it is the best of the lot to the urologist. Whether it is colon bacillus or the gonococcus, it is the most effective drug to date and attains clinical and bacteriologic recoveries surprisingly quick. His charts showing the forty-eight-hour blood concentration studies of these various drugs are, alone, of great value, and he is to be congratulated for presenting it so clearly. Dr. Borst seems to have reason to throw sulfapyridine out of the urologist's armamentarium—I agree with him. Some of its complications are too frequent and too annoying to encourage its further use. A few months ago I used it on a young man with a terrific poly-arthritis complicating a subacute gonorrheal urethritis. His pains increased to such an extent that he actually became uncontrollable. At first it was confusing to determine whether the arthritis was getting worse or whether the drug was producing the severe cramplike pains. Upon stopping the drug, the alarming picture subsided. He went on to complete recovery after changing to sulfathiazole.

Dr. Nesbit has given us his usual masterly address. He has left little to discuss. His remarks regarding pyelographic studies in pyelonephritis are interesting and, indeed, important, especially, as he has said, as a guide in our prognosis. Two frightening experiences, however, have taught me to be just a little less anxious to make pyelograms in the presence of an acute infection without first attempting to quiet the flame either by acidification or by sulfathiazole treatment. In the 2 cases easily recalled to mind, pyelography was done at the time of the first urologic study—1 of these, a young woman, showed a temperature of nearly 106.5 F. in less than twenty-four hours following pyelography—the other, a young man, had a temperature of 107 F. the following morning. Both recovered, fortunately, leaving me, at the moment, the sickest of all. A word of warning therefore seems rather timely, especially in relation to pyelography in the presence of burning fire. It is much safer to let the flame die down and then proceed with the pyelogram.

There is one point in Dr. Nesbit's paper upon which I cannot entirely agree. I believe treatment is much more than a prophylaxis against later recurrences. Many cases that have been followed and treated over a long period of time with frequent cultural check-ups have never, so far as I know, shown the slightest tendency to recur. We must definitely treat these patients over a longer period of time with many more follow-up visits than are in vogue at the moment. These patients must be taught that the care of an infected kidney is fully as important to them as diet and insulin are to the diabetic.

I know that Dr. Nesbit has studied urinary infections for many years—from the days preceding the ketogenic diet, acid therapy, etc.—and I am sure he will agree that all of our strenuous efforts of those days have practically been shat-

tered by the newer almost specifics, such as sulfathiazole.

Dr. Edgar Slotkin's paper was excellently presented. He has clearly shown us the importance of knowing whatever the existing pathology may be. I believe that this one fact of knowing the pathology, anomalies, etc., is the outstanding part of his paper, for it is as important in children as it is in adults.

Dr. Francis N. Kimball, *New York City*—This symposium, which has been so clearly presented by Drs. Nesbit, Borst, and Slotkin, has been particularly interesting to me.

The high incidence of congenital anomalies in children predisposes them to the menace of partial or complete interference with the normal flow of urine.

Campbell found a 30 per cent incidence of anomalies in 580 cases of chronic pyuria. Dr. Slotkin's study of pyelonephritis in children further emphasizes the absolute necessity for a complete urologic examination in each case of persistent pyuria in children.

All of us, I believe, will agree with Dr. Nesbit in the prevention and early treatment of pyelonephritis. A large number of cases seen by us can be attributed to some foci of infection, and I would add to Dr. Nesbit's list of etiologic factors such foci as infected teeth and tonsils.

The pathology of the chronic stage, which he so accurately describes, certainly suggests the relationship of pyelonephritis, both unilateral and bilateral, to hypertension. Although it is true that the extent of the pathologic changes in the renal parenchyma is not always visualized in the pyelogram, in many cases the deformity in the architecture offers a good working index. If the degree of deformity in the pyelogram is a representation of the amount of cicatrization and pathologic changes in the interstitial structures, tubules, glomerular tuft, and capsule of the kidney, then the results may well be in accord with Dr. Harry Goldblatt's theory of renal ischemia. In his original monograph, "Experimental Hypertension Induced by Renal Ischemia," he states: "It is probable that the hypertension associated with unilateral or bilateral pyelonephritis in children and adults occurs only in those cases in which there is associated vascular sclerosis or in which the inflammatory disease produces the same effect on renal circulation as does vascular disease."

Several investigators have stated that there is no correlation between hypertension and renal function. In other words, impaired renal function does not imply the presence of hypertension. I should like to ask Dr. Nesbit what his experience has been in the relationship of renal function to hypertension. Also, I am particularly interested in hearing what results he has obtained in treating by surgery the unilateral diseased kidney associated with hypertension.

While it is true that 70 to 90 per cent of the invading organisms of the kidney will be found to be of the colon group, we do not place entire reliance on the stained specimens. There are instances in which the stained specimens will reveal the presence of organisms that may fail to grow on the various culture mediums. Nevertheless, we feel that culture methods should be done to study and isolate the specific organism present. This is particularly important in the

use of the chemotherapeutic agents at our disposal.

Dr. Borst has pointed out that no single drug has been discovered which may be used for all types of urologic bacterial infections. However, he has most ably shown us the indications, the contraindications, the dosage, the optimum hydrogen-ion concentration, and the chemotherapeutic agent that is superior in its effectiveness against a particular isolated organism.

Rules Governing the Award of "The Foundation Prize" of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons

(1) "The award which shall be known as 'The Foundation Prize' shall consist of \$150."

(2) "Eligible contestants shall include only (a) interns, residents, or graduate students in obstetrics, gynecology, or abdominal surgery, and (b) physicians (with an M.D. degree) who are actively practicing or teaching obstetrics, gynecology, or abdominal surgery."

(3) "Manuscripts must be presented under a nom-de-plume, which shall in no way indicate the author's identity, to the Secretary of the Association together with a sealed envelope bearing the nom-de-plume and containing a card showing the name and address of the contestant."

(4) "Manuscripts must be limited to 5,000 words, and must be typewritten in double spacing on one side of the sheet. Ample margins should be provided. Illustrations should be limited to such as are required for a clear exposition of the thesis."

(5) "The successful thesis shall become the property of the Association, but this provision shall in no way interfere with publication of the communication in the journal of the author's choice. Unsuccessful contributions will be returned promptly to their authors."

(6) "Three copies of all manuscripts and illustrations entered in a given year must be in the hands of the Secretary before June 1."

(7) "The award will be made at the Annual Meeting of the Association, at which time the successful contestant must appear in person to present his contribution as a part of the regular scientific program, in conformity with the rules of the Association. The successful contestant must meet all expenses incident to this presentation."

(8) "The President of the Association shall annually appoint a Committee on Award, which, under its own regulations, shall determine the successful contestant and shall inform the Secretary of his name and address at least two weeks before the annual meeting."

JAS. R. BLOSS, M.D., *Secretary*,
418 Eleventh Street, Huntington, West Virginia

VENEREAL DISEASE CONTROL FOR NATIONAL SECURITY

An intensified campaign to prevent the spread of syphilis and gonorrhea has been launched by the Division of Syphilis Control as an aid in the state's program for health in defense, says *Health News*.

State health officers have been charged with increased activity in syphilis control, particularly in cities, since it is in populous centers that syphilis occurs most frequently. Sulfathiazole has been made available without charge to every physician in the state. Consultants from the State Department of Health have doubled their activities in defense areas.

The area around the military training center at Pine Camp near Watertown has received special

attention. Close coordination with army medical officers has effected constant interchange of information. Additional personnel from the Department has been provided to assist in keeping infected persons under treatment, finding disease carriers, stimulating the establishment of treatment stations in cities, and putting into operation all known methods to prevent the spread of the disease. Local and state police have responded heartily to the request of the Department that prostitution be repressed stringently by every available means with the result that the number of both professional and clandestine prostitutes has been reduced to a new low point.

SOME COMMON PROBLEMS IN THE MANAGEMENT AND DIAGNOSIS OF CONTACT DERMATITIS

ALBERT R. McFARLAND, M.D., Rochester, N. Y.

THE purpose of this paper is to emphasize some characteristics and peculiarities of contact dermatitis which are quite often not recognized by the general practitioner and also sometimes overlooked by the dermatologist. No claim for originality is made for these observations. They are all mentioned in such recent texts as Sulzberger's *Dermatologic Allergy*¹ and Schwartz and Tulipan's *Occupational Diseases of the Skin*,² as well as numerous articles in recent dermatologic literature. In order to orient ourselves it might be well to mention the usual classifications of dermatitis and eczema which are ordinarily recognized. These are: seborrheic dermatitis, eczematoid ringworm, infantile eczema, chronic atopic eczema, the lymphoblastomas, general exfoliative dermatitis of either toxic or unknown origin, and contact dermatitis. I shall confine my comments to the last group.

The following are characteristics of contact dermatitis which I think are of value to re-emphasize and which are phenomena often overlooked and, at times, difficult to explain. As has been emphasized by Sulzberger,¹ we do not have the least idea why a certain individual is allergic or reacts to a contact irritant while another individual does not. I make this statement realizing, of course, that various hypotheses have been advanced and that various factors have from time to time been mentioned as possible causative factors.

The first phenomenon is that an individual may apparently become sensitive or allergic to a contact substance after a long period of apparent immunity. It is frequently stated by patients that they are relatively free from poison by dermatitis over a period of years and then may rather suddenly become quite sensitive. I have recently encountered the case of a dentist who practiced his profession over fifteen years before becoming allergic to mercury used in amalgam fillings. His skin has now become so irritable that an open bottle of mercury left in the same room with him will cause definite symptoms of itching and choryza. Undertakers are encountered who have been in the business for many years without trouble and then become sensitive to formaldehyde, after which the individual may

not even be able to go into the room where there is the odor of formaldehyde.

A second point of interest is that there is likely to be an increasing severity of the dermatitis following repeated exposures. Coincident with this increased severity of attacks may be noted the development of a multiple sensitivity. I have seen the case of a woman who developed a dermatitis of the palms from the ink used in the manufacture of blank checks. Patch tests were strongly positive, and at the beginning the condition would clear completely when she stopped work. However, after several exacerbations, it was found that she would develop a dermatitis from contact with soap and also from wool gloves. Careful protection was necessary over a period of many months before the condition eventually subsided.

As already mentioned, the fact is often overlooked that almost unbelievably small quantities of material may act as an irritant. It has been stated that the concentration of a substance necessary to cause contact dermatitis in some people may be about equivalent to the concentration of odors from a volatile substance. It is, therefore, not always necessary to have gross contact with a chemical in order to produce irritation of the skin.

Another fact worthy of note is that the sensitivity to external contacts does not by any means parallel the sensitivity to the same material injected, ingested, or even inhaled. An individual may be extremely allergic to taking aspirin tablets and, at the same time, a patch test on the skin to aspirin tablets may be negative. Ragweed pollen when inhaled into the lungs may cause asthma, and the same individual may have a negative patch test to ragweed pollen. Even in the case of arsphenamine dermatitis, it is quite possible to have a patient who will develop a severe dermatitis from injections of small amounts of arsphenamine and still have a negative patch test to arsphenamine on the skin.

The question of alternating periods of sensitivity and immunity has been the subject of much discussion. An explanation of this phenomenon would probably tell us why any individual is ever allergic to anything. It does seem to be a fact, however, that occasionally patients are observed who at one time

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

are irritated by some substances and give positive patch tests and at other times do not. We have even seen cases of baker's dermatitis in which, in spite of continued exposure to baking materials, the patient would have periods of several months or longer of comparative freedom from trouble, only to be followed by an acute exacerbation.

A dermatologic colleague of mine told me of an interesting observation on his own skin. A certain furniture polish was used on the arms of his office chair, and he noticed that occasionally he developed a dermatitis on his forearms. He experimented with patch tests on himself with this material and concluded that at times, when he was under extreme nervous tension, the patch tests would be positive and the dermatitis would develop. At times, when this tension was absent, patch tests would be negative and he apparently would not be bothered by the polish. This example may give some concrete evidence to the ideas that have been recently expressed by Stokes³ and by Becker⁴ regarding the psychoneurogenic factors underlying certain dermatoses.

Another fact worth emphasizing again is that a dermatitis on one part of the body may so sensitize the entire skin or distant parts of the skin as to render them susceptible to external irritation. I think we have all seen such examples as a case of hair-dye dermatitis which eventually terminated in extensive involvement of the entire body or of a surgical case where an iodine dermatitis developed and where irritation of the knees and elbows readily followed from the rubbing of bed sheets. Experimentally, this phenomenon is seen in transepidermal absorption, where a patch test may be only slightly positive or even negative but will result in a flare-up or exacerbation of an original dermatitis. Incidentally, this calls to mind the occasional danger of patch testing cases where an extensive dermatitis already exists and where the possible offending agent is an essential irritant. Knowledge of this skin peculiarity should call to mind the importance of noting the original site of the dermatitis in taking a patient's history rather than paying too much attention to the areas involved at the time of examination.

Substances Responsible for External Irritation

External irritations may be roughly divided into two classes: first, those that are essential irritants, such as strong caustics and

acids; second, those that are not essential irritants but to which the patient may be allergic. Almost weekly reports are appearing in periodicals and journals of a dermatitis caused by some unusual substances. It is probably not far from the truth to state that almost any known substance—animal, vegetable, or mineral—may be capable of causing a dermatitis in some one individual at some particular time. While this makes the task of finding the offender difficult and, at times, impossible, yet it also impresses us with the fact that continued search and painstaking detective work may be rewarded.

It is not my purpose to give any long list of unusual materials that have been found to be skin irritants. However, I should like to enumerate a few irritants that I have encountered in practice which illustrate the novel and bizarre. They include: newspaper ink, Japanese lacquer, carbon paper, resinous materials used on new underwear and pajamas, plastics, dentures, tooth paste, jewelry, cosmetics, deodorants, shoe dyes, salad dressings and vegetables, feathers, varnish, latex rubber gloves, watch-cleaning materials, photographic supplies, insecticides, cocobolo wood, "live glass" suspenders and belts, effervescent waters, nail polish, and contraceptive jellies. Helpful lists of common irritants are found in recent textbooks by Sulzberger¹ and also by Schwartz and Tulipan.²

Points to Be Emphasized in Making Patch Tests

The pitfalls and limitations of patch testing have been well emphasized in the literature. One should keep in mind the following pertinent facts in doing patch testing. First, the conditions under which the patient is exposed should be duplicated as near as possible with regard to the dilution of the material, length of application, and the location of the patch tests. Second, patch testing of acute generalized cases where the probable offending substance is an essential irritant should be performed with great caution. Third, a positive patch test does not always mean that the cause of a dermatitis has been discovered. Fourth, a negative patch test does not always exclude the substance as the actual cause of the trouble. Fifth, where essential irritants are involved it may not be practical to do patch testing at all, and one must resort to the clinical tests of removing the patient from his surroundings for a suitable length of time.

Relation of Diet to Contact Dermatitis

Although the patient is often certain that a dermatitis is due to some food ingested, the more one sees of dermatitis, the more one is convinced that foods are seldom an answer to the problem. Drugs may, of course, produce a dermatitis, although their reaction is more likely to be that of a transient toxic erythema rather than a true dermatitis. The arsenical group is more likely to produce a true dermatitis, such as is seen in exfoliative dermatitis following the administration of arsphenamine. It has been my experience that almost never is the ingestion of a food a major factor in producing dermatitis. Even where scratch tests give positive reactions to certain foods, one seldom sees any change in the clinical picture by removing such food from the diet. Even in the case of chronic atopic eczema, it is usually discouraging to try to correlate the findings resulting from scratch tests with any change in the eczema for either better or worse.

Immunization Against Contact Irritants

In my opinion it is doubtful if anything effective can be done at the present time in the way of active immunization against contact dermatitis. The one exception to this general statement is in the case of some of the vegetable oils, such as the oleoresin of poison ivy and certain other weeds. Even in this field only partial success can be claimed.

Clinical Approach

In the clinical approach to a case of chronic dermatitis the following facts should be kept in mind. First, practically any substance that can be mentioned may produce a dermatitis in some one individual at some particular time. Second, the unusual and bizarre should always be kept in mind, as well as the more common and usual irritants. The detective ability of a Sherlock Holmes is probably the greatest asset that a dermatologist can have in handling these cases. All the skin testing in the world is of little value in comparison to a careful painstaking history.

After a list of possibilities have been obtained from the history, confirmation by patch testing is then in order. Third, time should be taken to explain to the patient the nature of his trouble and what you are trying to do in solving his difficulty. It is usually necessary first to disillusion him with regard to ideas that he may have as to the etiology, such as "acid in the system," "indigestion,"

"food sensitiveness," "bad blood," etc. Curiously enough, the patient often takes a negative attitude and you feel that subconsciously he is defying you to solve the problem. Many times I have not succeeded in getting anywhere on the first visit, but, after getting the patient to think along these lines, he will return in a week or two stating that he forgot to mention certain things and wondered if possibly the primrose in his room or the paint that he handled in his garage might have anything to do with his trouble. Often, by assuming the attitude that you are at the end of your rope and cannot imagine what the irritant may be, the patient may come across with some enlightening information. I, of course, have no objection to his taking credit for solving the problem. Occasionally, the frank malingerer may be encountered, but his attitude usually makes one suspicious. I find that the intelligent patient whom you are convinced is sincere may be taught to do simple patch tests on himself. I have frequently had this type of patient make lists of probable substances and do the tests on himself, often with gratifying results. This increases his interest in the problem, as well as saving him unnecessary office calls. Finally, if all efforts fail, it may be necessary to remove the patient completely from his surroundings, such as having him change his job, go on a vacation, or stay with a relative for a week or two.

Treatment

The ideal treatment is, of course, to find and remove the irritant. This is a simple matter in the case of a primrose in the house, a new pair of dyed pajamas, or a certain brand of rouge. The case of occupational dermatitis, however, presents a difficult and often insurmountable problem. A baker who is sensitive to flour but who has a family to support and knows no other type of work may have to choose between more or less continuation of his dermatitis or trying to learn some other type of occupation. Likewise, the dentist who becomes allergic to mercury may find his professional career practically ruined. These cases offer serious problems where compensation is involved, and we look forward hopefully to the time when some method of desensitizing these individuals can be successfully carried out.

In the meantime, it is by no means a waste of effort to carry out symptomatic treatment. Very often, the use of suitable local applications or the judicious use of x-ray therapy may

make all the difference between recovery and continued invalidism.

In conclusion, I might state again the well-known fact that what we need to know is why certain individuals have a sensitivity to certain external irritants. At present, we must admit that we have not the slightest adequate knowledge as to why one person develops a dermatitis from exposure to primrose and another does not. Factors that have been considered from time to time in the production of this sensitivity are: nervous instability; an imbalance of the potassium, calcium, and magnesium salts in the tissues; the overproduction of histamine; disturbances in fat metabolism; glandular dysfunction; and faults in pigment metabolism. None of these hypotheses, however, have given us an adequate answer to our problem.

Summary

1. Some peculiarities and characteristics of contact dermatitis are enumerated.
2. Almost any known substance may at times produce a dermatitis in some one individual. A list is given of a few unusual causes of dermatitis which serves as an example of problems involved.
3. Some technical points involved in the performance of the patch tests are emphasized, and also certain dangers in its use.
4. While symptomatic treatment is of value and removal of the offending substance may be curative in individual cases, our great need is to know the underlying cause of cutaneous sensitivity.

Discussion

Dr. Howard Fox, *New York City*—The subject of contact dermatitis is an important and practical one to which hours instead of minutes could well be devoted. It is constantly broadening by the discovery of new substances that may

sensitize the skin and by unusual ways in which this may occur. For instance, sensitization may take place by indirect contact through another person who is not affected, as shown recently by Niles. Even a dermatitis apparently due to lipstick has been shown to be due to the metal container and not the lipstick itself.

Dr. McFarland mentioned a list of substances that only occasionally act as allergens, examples of which he has personally encountered. One of these was carbon paper. Sensitization to this substance must be rare; at least, I have been unable to prove a single case of dermatitis from this supposed irritant.

Dermatitis of the eyelids, especially in women, naturally suggests sensitization from cosmetics. We are all aware that nail lacquer may be the offending agent in such cases. In a recent paper read before the American Dermatological Association, Dr. Osborne reported the astonishing number of 100 proved cases due to this type of irritant. For a number of years I have told some of my patients, in a joking way, that their dermatitis was caused by nail polish. There was probably at times more truth than fiction in my remarks. It is astonishing to see how rapidly a dermatitis, due to nail lacquer, of the face or other parts will disappear when the patient stops using this particular kind of personal "adornment."

We all agree about the value of patch tests in contact dermatitis but recognize their limitations. While the positive reaction usually appears within forty-eight hours, it may at times be delayed for days or even weeks. In a recent report by Kulchar, a patch test to nupercaine ointment was positive only at the end of forty-five days.

Dr. McFarland spoke of a flare-up of the original site of an eruption following the application of a patch test due to transepidermal absorption. Such a case might possibly have a medicolegal implication. It seems to me, however, that when a patch test is indicated, and when it is properly performed, the physician would be absolved from any charge of negligence.

One of our most difficult problems is to differentiate an occupational dermatitis of the hands from a fungous infection (dermatophytide). In this regard it is refreshing to read the statement of Sulzberger and Wolf that "the diagnosis of eczematous dermatophytide is being overworked." This is especially true of compensation cases. In my opinion an "ide" eruption, especially if extensive, can be reasonably excluded if a trichophytin test is negative.

LECTURE ON DIETETICS

The Mary Swartz Rose Memorial Lecture, sponsored by the Greater New York Dietetic Association, will be held at The New York Academy of Medicine on February 3 at 8:15

p.m. The speaker will be Dr. C. A. Elvehjem, professor of biochemistry, University of Wisconsin, and his subject is "Natural Foods in the American Dietary."

DIVERTICULUM OF THE FEMALE URETHRA

MAURICE RASHBAUM, M.D., and GABRIEL P. SELEY, M.D., New York City

DIVERTICULA of the female urethra are rare. Among 234 patients investigated by Stevens¹⁵ because of symptoms referable to the urinary tract, there was 1 case of urethral diverticulum. Some authors have expressed the belief that diverticula of the urethra are invariably acquired, while others consider a congenital origin probable in some cases. No definite criteria have been described by which a congenital diverticulum may be distinguished from an acquired one. The two most common causes of acquired diverticulum are injury during parturition and dilatation above an obstruction in the urethra (stricture or stone). Hinman⁵ believes that the terms "urethrocele" and "diverticulum" best designate the two extreme types of urinary pouches, the one wide open into the urethra and the other with a narrow or slitlike opening.

The symptoms of urethral diverticulum may include any or all of the complaints commonly associated with lesions of the lower part of the urinary tract, such as dysuria, incontinence, pyuria, frequency, etc. When one observes a cystic swelling in the region of the urethra, the possibility of urethral diverticulum should be considered. Palpation confirms the cystic nature of the swelling and, at times, pressure will cause a discharge of turbid urine from the urethral orifice followed by disappearance of the mass. The diagnosis is easily verified by x-ray visualization with the aid of contrast mediums injected either into the urethra or directly into the mouth of the diverticulum. A urethral catheter may be used for the latter procedure. Sodium iodide in 5 to 12 per cent aqueous solution or 60 per cent hippuran in jelly may serve as the contrast substance. The latter was used in our case. Young and McCrae¹⁶ suggest filling the bladder with radio-opaque material and then taking the x-ray while obstructing the external urethral orifice as the patient attempts to void.

Nonoperative treatment of urethral diverticula by carbolic acid or by the injection of sclerosing solutions is not advocated. Electrocoagulation, fulguration, or cauterization are usually of no value.

Preoperative treatment is aimed at con-

trolling the urinary infection. Some authors have considered it necessary, before operation on the diverticulum itself, to establish bladder drainage, either vaginally or suprapubically, in order to reduce the danger of contaminating the suture line in the urethra with infected urine. Routh¹² in 1890 suggested leaving the urethral defect open after excision of the urethral diverticulum in cases with severe urinary infection. Neither this procedure nor a preliminary drainage operation is necessary under ordinary conditions. Urinary infection can usually be controlled by preoperative treatment, including oral administration of urinary antiseptics and bladder irrigations and instillations.

Numerous operative procedures have been employed for the cure of urethral diverticulum. If it is suspected that the diverticulum contains a calculus, it is advisable to open the diverticulum first and to remove the calculus before excising the sac. Neil⁹ advised invagination of the thinned-out sac followed by a fascia-lapping procedure. However, in doing this there is danger of obstructing the urethra by the infolded redundant sac. Young¹⁶ performed simple incision of the sac with carbolic acid and reported a successful case. The choice of suture material varies with the operator and in our opinion is of minor importance if the dissection is adequate to provide good flaps without tension. After operation, an indwelling urethral catheter is employed, connected to an apparatus for continuous bladder drainage and irrigation. The technic introduced by Duke at St. Mark's Hospital, London, England, and recently popularized by Colp¹ in this country for the prevention of bladder complications after major proctectomy was used in our case. After the catheter is removed and when the patient is voiding normally, it may be desirable to pass urethral sounds. This should not be done before twenty days after the operation.

Case Report

Mrs. M. R., a Puerto Rican, aged 39, was first admitted to City Hospital in March, 1938, complaining of dribbling and incontinence of urine following the birth of her last child four years before. Obstetric history included seven pregnancies, four terminating in miscarriage and three in the birth of full-term babies. The first child was

Attending gynecologist and assistant visiting gynecologist, respectively, City Hospital.

FIG. 1. Showing urethrocele before operation.

born in 1926 after a difficult labor. An episiotomy was performed but delivery was spontaneous. The second child was delivered by forceps in 1928. Her last child was born in 1934 after a fairly easy labor, except that catheterization had to be performed during labor before progress could be made. Immediately following this delivery her urinary symptoms began. She continually wet herself with urine during the day and also when in bed at night. The patient voided in small amounts several times during the day and during the remainder of the day dribbled urine upon the least movement. There was also burning on urination. One year before admission she began to have pain in the left costovertebral angle which radiated to the left upper quadrant and down to the left leg. This pain came in attacks associated with nausea and vomiting. Six months later a left nephrectomy was performed for calculus disease of the kidney. Dribbling of urine and burning on urination continued until her admission to the Gynecological Service of the City Hospital.

A urethral diverticulum was demonstrated by urethral endoscopy and by the injection of radio-opaque material into the diverticulum. On April 22, 1938, an operation was performed under caudal anesthesia. A bulge 2 cm. across was present a distance of $2\frac{1}{2}$ cm. from the urethral meatus. The sac was opened for a distance of 2 cm. and the walls were then invaginated. The anterior vaginal wall was repaired using interrupted No. 2 chromic sutures. Following this procedure the patient was not re-

lieved of her symptoms. She was discharged on May 5, 1938.

She was readmitted on June 27, 1938, complaining that the dribbling was worse than before the operation. Examination at this time revealed a swelling in the midline of the anterior vaginal wall 2 cm. proximal to the urethral orifice. It measured 2 cm. in diameter and was covered with smooth epithelium quite unlike normal vaginal mucosa, nontender, and not bleeding. Distal to this lesion was a puckered scar of the previous operation. There was a slight relaxation of the urethra itself. The mass was fluctuant, and on pressure over it turbid urine escaped from the urethral orifice. A continence test was performed and the patient was found to have no loss of voluntary sphincteric control. The urinary dribbling was believed to be due to an overflow from the diverticulum, which filled with urine each time she voided and then continued to leak. Preoperatively, 10 per cent argyrol was instilled into the diverticulum each day.

The second operation was performed on July 15, 1938, under spinal anesthesia. The patient was placed in the lithotomy position and a catheter was inserted into the bladder. Elliptic incisions 4 cm. in length were made through the anterior vaginal wall on each side of the old scar. The diverticulum was dissected free on all sides. The urethra and the urethrovaginal junction were then freed from the vaginal wall and from the medial surface of the pubic ramus on each side. The finger could readily be passed on either side of the urethrovaginal junction into the space of Retzius. When the dissection of the diverticulum, urethra, and urethrovaginal junction had been completed, the diverticulum was excised at its neck, leaving an opening in the inferior urethral wall about 1 cm. wide and $1\frac{1}{2}$ cm. long. A series of transversely passed interrupted zero chromic catgut sutures closed the defect in the urethra. In passing these sutures, care was taken to avoid including the urethral mucous membrane. A second layer of sutures approximated the periurethral tissues. The severed edges of the vaginal wall were then brought together by interrupted chromic catgut sutures, again passed from side to side. Following this, an ordinary No. 18 French soft rubber catheter with a cuff 6 cm. from its extremity was inserted into the bladder, and the cuff was fixed to the vestibule with two silk sutures. An iodoform gauze packing was placed in the vagina.

The "Duke" apparatus was connected to the indwelling catheter, and the bladder was irrigated every two hours with 50 cc. of 1:5,000 acriflavine solution. On the twelfth day the catheter was removed. The patient was unable to void and catheterization was performed. She voided several ounces the following day, but because of pain in the region of the urethra the catheter was reinserted. On the seventeenth

postoperative day, the patient was voiding well and the residual urine measured only 1½ ounces.

The wound healed by primary intention. On discharge from the hospital there were no urinary symptoms. Examinations at intervals during the following six months showed no evidence of recurrence. The patient had perfect urinary control, and continence tests revealed a normal function.

The pathologic report was as follows: The tissue was 2½ by 2 by 1 cm., consisting of a section of fibrous tissue lined on one side by squamous epithelium and the other side by transitional epithelium. There was a marked round-cell and polymorphonuclear infiltration.

Summary

1. A case of urethral diverticulum in a woman is presented, with operative cure.

2. Complete excision of the diverticulum should be performed before any repair is attempted.

3. The need of complete mobilization of the urethra and urethrovesical junction without tension on the suture line is stressed.

4. The use of continuous bladder drainage and irrigation after operation is advocated to prevent contamination of the suture line by infected urine.

ESSENTIALS OF A SCHOOL HEALTH PROGRAM

In an address at Bayport, L. I., New York, Dr. William H. Ross listed six basic principles common to all school health programs.

1. Every child entering school should present a certificate of health from the family physician.

2. Periodic health examination of all pupils in public, private, and parochial schools.

3. Thorough follow-up work for the correction of remediable defects so that they may be understood and corrected by the parents but, if unable, by some other agency. Keep in mind that the school is an adjunct to the family and does not replace family responsibility.

4. Specific health education on the care of teeth by the employment of a dental hygiene teacher, who will teach children the care of the teeth. Dental caries is one of the most important causes of poor health.

5. A continuation of the use of public health nurses under the follow-up system now established to cover all children to help in general health education and the control and prevention of disease and the problems of nutrition and to follow up the correction of physical defects and the home environment.

6. The use of the Mental Hygiene Unit of the County Department of Health for child guidance either in clinics or by consultation.

Mental illness is beginning to have careful attention in this country. Suffolk County spends \$500,000 a year to take care of its mental sickness. It is the first county in the United States to recognize mental sickness as a public health problem. It is the first county in the United States to set up a mental health organization.

CHRONIC HYPERTROPHIC OSTEOARTHRITIS IN THE CERVICAL SPINE WITH RADICULITIS

A Report of 40 Cases with a Review of the Literature, Together with Some Notes on Effective Methods of Treatment—Part II

LE MOYNE COPELAND KELLY, M.D., F.A.C.P., New York City

Special Symptoms Ordinarily Not Ascribed to Osteoarthritis in the Spine

Headache.—Of the multitude of symptoms that arthritis of the cervical spine can produce, probably none has received so little attention as headache. In the older literature^{34,*} this type of cephalalgia was commonly referred to as "indurative or rheumatic headache" and was generally loosely ascribed to a "fibromyositis of the fascia, pierced by the cervical nerves as they pass superficially toward the scalp." Holbrook's²³ complaint that textbooks and diagnostic hints make little, if any, mention of arthritis as a cause of headache is well founded. His description in 1927 of a series of patients with headache, in whom osteoarthritic changes were consistently found in the first three cervical vertebrae, was a great contribution to our knowledge of this subject. Other students of the problem have confirmed these findings, and Gunther and Kerr¹⁸ stated that they never found headache except in those cases having at least some involvement of the first three cervical vertebrae, even though the lower cervical vertebrae did, in many cases, show much more advanced changes. (Only half of our 16 cases complaining of headaches showed any involvement of C1-3.)

They describe this head pain as beginning in the neck and radiating up over the occiput toward the temporofrontal area. It is usually brought on by movement of the head and is generally sharp and piercing in character. Often, there is an associated tenderness, soreness, burning, or a dull aching sensation in one or another area of the scalp. Thirty-one (52 per cent) of Bisgard's⁵ cases showed this characteristic type of occipital or suboccipital headache, which radiates forward widely over the scalp. Hartsock²¹ especially emphasized the fact that not all of these cases will show definite x-ray evidence of arthritis in the cervical spine and that if we insist on positive x-ray findings before we make a diagnosis of this condition as the causative factor in the headache we shall miss many

of these cases. This is well illustrated by Case 8.

Case Report

Case 8.—H. F., aged 74, was first seen in a dispensary March, 1935, complaining of pain in the shoulders and hands. A physical examination showed only crepitus in the shoulders and knees. A diagnosis was made of a generalized osteoarthritis and the patient improved under conservative treatment. Six months later, however, she returned complaining of pain in the right shoulder which radiated to the wrist. This cleared up rapidly with heat. Since a previous x-ray had shown marked osteoarthritic changes in other parts of the spine, an examination of the cervical spine at this time (November, 1935), demonstrating only minimal changes in this area, was considered to exclude osteoarthritis as a probable cause of the patient's symptoms.

Some three years later (October, 1938) she came in again complaining of a pain on the right side of her neck, which radiated up over the right occiput to the temple, across the forehead to the left side of the scalp, and back to the neck. She described it as a "sort of twinge" that she experienced whenever she turned her head. These symptoms gradually disappeared after the application of heat, and the patient was not heard from until a year later when she returned complaining of the same pain in her neck. This was now associated with a "clicking sound" and was brought on by any motion of the head, particularly on arising from bed in the morning. She described it as a sharp pain that lasted an hour or two and "made her eyes water and her eyeballs burn." Re-examination of the eyes was essentially negative, and a report was received from the ophthalmologist that the "headaches are apparently not due to the eyes."

She was then seen by an orthopaedist who advised careful manipulation followed by physical therapy and gentle massage. This was carried out, and the patient reported temporary relief from the heat but stated that any sort of massage tended to aggravate her symptoms. After three months of conservative treatment, she was not improved; in fact, she complained of "constant headache, pain at the base of the skull, and terrible stiffness in the neck, especially in the morning," so she was sent to a neurologist. He stated that her osteoarthritis was *not* a factor in her neurologic complaint and that all her symptoms were due to carotodynia. Another neurolo-

* For references see Part I, January 15 issue. Part III will appear in the February 15 issue.

gist, however, suggested that *in spite of the lack of x-ray findings of osteoarthritis in her cervical spine* the patient might benefit from radiation therapy to that region. Since nothing else had helped her, she consented to this form of treatment and received 1,800 r units (in air) over a period of three weeks. When last seen, one year later, she was almost entirely relieved of symptoms.

Altogether, this patient was seen by eight different physicians before a diagnosis as to the cause of her headache was made.

The usual story^{21,23} is that the patient describes periods of suffering alternating at first with days or weeks of relative freedom, but, later on, there is a tendency to long sieges of discomfort, so that eventually the patient may have a headache all day and every day. As a rule, it comes on in the early morning and may awaken the patient from sleep. Relaxation of the supporting structures of the spine (viz., as in sleep), increase in tension of the neck muscles from long hours of sedentary work, eyestrain, and exposure to draughts are given as exciting causes. In fact, Hartsock²¹ cited a case in which something as apparently insignificant as the removal of so small an amount of protection from cold as that afforded by the human hair resulted regularly in an attack of headache, which happened every time the patient had his hair cut. He concludes that "where all other evidence points to this disorder (viz., marked tenderness at the point of attachment of the trapezius muscle to the skull, etc.) and where repeated temporary benefit is obtained from physiotherapeutic measures one should never hesitate to make a diagnosis of osteoarthritis of the cervical spine." It is his considered opinion that if the physician would think of this possibility in every case of persistent head pain a great many cases could be removed from that large and baffling group that we now term "chronic idiopathic headache."

Other Pains in the Head (Facial Neuralgia, Earache, Sore Throat, "Sinus Pain," and "Eye Trouble").—That pain in the face along areas conforming to the distribution of the sphenopalatine and vidian nerves (viz., orbit, maxillae, and posterior nasopharynx) may result from several widely different types of irritation in the neck is a point that has not been considered often enough, particularly by those who are most concerned with the problem of pain in the head.

For example, Sluder¹⁰ and Clerf⁹ have explained certain pains in the face solely on the

basis of direct stimulation of ganglia by lesions nearby, while the role of lesions occurring at a distance (viz., in the neck) was not even considered (where no definite cause could be located it was simply termed "idiopathic"). Vail⁴⁵ referred to a type of neuralgia associated with infection of the sphenoid sinus and seen in the area of distribution of the vidian nerve. This he described as a "sharp pain felt deep in at the root of the nose and in, around, and behind the eye. From here it radiates across the temple to the ear, mastoid area, and in some severe cases even down the neck to the shoulders and arms." But he, too, did not mention a focus of irritation more distant than the nearby sinus as a possible initiating factor in the production of this train of symptoms. It was not until Ruskin³⁷ made a careful study of this whole subject that it became clear that the sphenopalatine ganglion syndrome of Sluder is not a distinct clinical entity at all but is really composed of four syndromes—maxillary, sensory facial, sympathetic, and local sphenopalatine (the ganglion cells proper)—and that in any given case these various syndromes are usually present in different combinations.

Hunt^{24,25} states that the neuralgic affections of the cranial nerves (see Figs. 1 and 2) may include such conditions as:

(1) *Geniculate neuralgia*, which affects the deeper structures of the face and produces sensation of painful pressure there (deep prosopalgia) together with pain in the deep posterior orbit, nose, and palate.

(2) *Glossopharyngeal neuralgia*, characterized by neuralgic pains in the area of distribution of the glossopharyngeal nerve at the base of the tongue and in adjacent regions of the throat.

(3) *Superior laryngeal neuralgia* (vagal in origin) with pains localized to the region of the larynx.

All these types of neuralgia may at times be accompanied by otalgia, and the clinical diagnosis in these cases is often involved and difficult.

Furthermore, Ussher's⁴⁴ studies suggest that there are certain, even more remote, "foci" that may cause identical "visceral" symptoms in the head. He maintains that such foci can consist of: (1) chilled cutaneous structures in the region of cranial nerves, (2) myositis of the cervical and upper dorsal muscles, and (3) articular derangements of the cervicodorsal spine. He has repeatedly demon-

strated that by the correction of factors that cause irritation of sympathetic fibers (which, he believes, act as channels for impulses from these relatively distant foci) he can give the patient complete relief of all symptoms. Moreover, such "visceral" symptoms can recur whenever any of the precipitating factors are allowed to return. He quotes Atsatt² in describing the pathways for these nerve impulses. According to these observers, herein lies the explanation of the pathway for pain in those patients with osteoarthritis of the cervical spine who give a history of unilateral symptoms such as hemi-crania or even at times a one-sided earache or sore throat. Just such a situation is illustrated by Case 7 (the picture in this patient was at first somewhat obscured by an osteoarthritis of the dorsal spine with abdominal symptoms, but, when it became apparent that the gastrointestinal complaints were on

a radicular basis, the cause of the head pain was easily determined).

Case Report

Case 7.—M. G., aged 68, was first seen in a dispensary in July, 1937, complaining of pain in the shoulders—worse on arising in the morning and during cold weather. She also complained of a headache that, she stated, she had had "off and on for 44 years." Orthopaedic examination revealed a diminution in motion throughout the dorsolumbar spine and crepitus in all her joints, but x-rays of the shoulders were negative. She was treated conservatively with physical therapeutic procedures but still complained of the same joint pains, constant headache, and frequent abdominal cramps. In February, 1938, she consulted an otolaryngologist for pain around and behind the right ear. He reported that there was no pathology in the nose and throat and that the "pain might possibly be due to a neuritis."

In October of that year, she was seen by an arthritis specialist who told her that nothing more could be done for her pains and advised her to see a "nerve specialist" about the headache. Subsequently, she was examined by two physicians, who could find no deviation from the normal. X-ray of the skull was reported negative and, thereupon, she was discharged as a "tense, unhappy, dissatisfied woman who is dependent and resents it." Eye examination at this time was negative, but the ophthalmologist noted that the headaches were frontal and worse upon getting up in the morning. Another examination of the eyes after a period of more than a year, in an effort to determine the cause of the headache—which had persisted up to this time and which was always aggravated by lying down—was reported to be negative, and the headaches were still considered to be "not due to eyes."

Special Note: The patient did not return thereafter until a year later, when she was seen by a gastroenterologist for a sharp pain in the epigastrium radiating to the right upper quad-

rant and up under the sternum. She stated that she had had it off and on for about two years. It would come on in cycles alternating "one week on, then a week off." A tentative diagnosis was made of chronic cholecystitis. However, the Graham test and gastrointestinal series were normal and the stool was negative for occult blood. Gastric analysis showed no free HCl after histamine, but the blood count was normal. Pelvic examination was entirely negative. No cause for the abdominal symptoms was found (x-ray studies of the dorsal spine had not been done).

I saw the patient in May, 1940, at which time she complained of "pain in the neck and middle of her upper back." Physical examination revealed crepitus in the neck, shoulders, and knees with little motion in the dorsal spine. An x-ray examination showed considerable osteoarthritis in the cervicodorsal spine with some cervical scoliosis. The middorsal vertebrae varied considerably in thickness. Having tried physical therapy over a long period of time without benefit, the patient consented to x-ray therapy, and this was given (1,400 r units in air) to the cervical and upper dorsal spine over a period of ten days. Two months later she reported that there was much less pain in the back of her head, that she had had no recurrence of earache, and that her neck muscles were now considerably looser. She stated that the vertical headache was somewhat diminished but still tended to increase toward the end of the day. A further course of six treatments (600 r units in air) was then advised, following which the patient said that "the pain on the top of her head, which had been there so long, had by now entirely disappeared."

This patient was examined by twelve physicians before the diagnosis was established.

If we accept the pathways as outlined by Ussher⁴⁴ as probable channels for the passage of impulses from those more remote lesions in the head and neck, we are thereby enabled to visualize more readily the great variety of pains in the head which can be produced by an arthritis of the cervical spine.

Pseudoanginal Pain.—MacKenzie²⁷ pointed out in his book on *Angina Pectoris* that the pain in the viscerosensory reflex associated with organic disease of the heart and the pain of a similar distribution but not associated with heart disease may resemble each other so closely that sometimes an exact differentiation can be made only by watching the progress of the case. Others⁴¹ confirm this difficulty in differentiating the exact cause of certain pains in the chest especially in those patients known to have both angina and arthritis of the spine. In 1926 Kilgore²⁸ discussed an "anginoid type of pain" and showed how it differs from true angina, but

he did not ascribe the syndrome to osteoarthritis of the spine. Hanflig²⁹ cited such a case in which x-ray pictures of the spine were reported negative but in which there was slight limitation of the neck movements in all directions. When the symptoms subsided after adequate physical therapeutic measures, he concluded that his patient had a cervical arthritis. He feels that there must be many patients who are treated mistakenly for years for heart disease whose symptoms are really due to arthritis of the spine with root pains. Other writers⁴³ also have reported having seen patients who had had a previous diagnosis of "aortitis" or "angina," but, in whom, after thorough study, all the symptoms were found to be due not to cardiovascular disease but simply to irritation of the lower cervical spinal roots.

The mechanism of pain referred to the precordial area as a result of irritation of these cervical roots by osteoarthritis of the spine has been clearly described by Nachlas²⁹ who reported 3 such cases in detail in 1934. According to this authority the pectoralis muscles are innervated by the lateral anterior thoracic nerve (C 6 and 7) and the medial anterior thoracic (C 8, D 1), while the teres, the subscapularis, and the deep portions of the latissimus dorsi muscles receive fibers from the long thoracic, thoraco-dorsal, and subscapular nerves (which are derived from the posterior roots of the lower cervical nerves, C 5-8). All of these, although primarily motor nerves, possess protopathic sensations, so that pinching of their roots by osteoarthritic changes in the spine can produce that which will be referred, in each instance, to the terminal portion of the nerve involved. In this case, since it is the nerves to the muscles lying on the chest wall which are affected, it becomes clear how a lesion in the cervical spine may result in *precordial* pain.

It was Henry Head²² who first presented in 1895 the hypothesis that motor nerves convey fibers of deep sensibility, but the existence in motor nerves of certain afferent fibers to the skeletal muscles was actually demonstrated first by the physiologist Sherrington.³³ He observed that a third to a half of all myelinated fibers in motor nerves are sensory, originate in the spinal root ganglia, and run directly to the muscle bundles.

Gunther and Sampson¹⁹ maintain that the differential diagnosis of precordial pain of a radicular origin from that of a visceral origin is largely made on the basis of a careful his-

tory. They state that "where pain in the chest is present as a result of spinal arthritis, it is consistently found in broad, beltlike zones along well-defined spinal root dermatomes and across the *back* of the chest as well as over the precordium." Moreover, symptoms may be present at the same time in the neck and shoulders, and these neck pains frequently radiate over the shoulder girdle to the *outer* aspect of the arm and forearm. X-ray study usually reveals some osteoarthritic changes in the upper dorsal or lower cervical spine (although this is by no means constant), and the patient almost invariably shows some clinical evidence of this disorder in other parts of the body. As a general rule, these cases get definite, though temporary, relief from heat and salicylates, while such measures as changing to a hard bed and immobilization in a Taylor brace or high back corset often give additional comfort. In this condition, the patient frequently reports that the pain in the left side of his chest, which comes on in the early morning hours, will go away if he can find a comfortable position in bed. However, some authors state that the pain and stiffness due to an arthritis of the neck tends to disappear after mild activity (viz., after "limbering up" in the morning), just as is the case in osteoarthritic conditions in any other part of the body.

On the other hand, if the precordial pain is visceral in origin, the nervous phenomena associated with cardiovascular pain tend to dominate the picture, viz., sweating, salivation, and urination. The patient is more apt to be vague about the exact localization of his chest pains (in contrast to the sharp localization in the root pain due to hypertrophic arthritis), and the response to effort will not be so good. Moreover, the nitrites and other vasodilators will afford this patient more relief than physical therapeutic measures. At times some confirmatory evidence may be obtained from the electrocardiogram and 6-foot plate. The necessity for this differentiation is well illustrated by Case 35.

Case Report

Case 35.—Mrs. L. G., a widow, aged 54, gave a history of pain across the left side of the chest and in her left shoulder whenever she attempted to comb her hair. This pain sometimes radiated down the inside of her left arm to the wrist and was often associated with a "pins and needles" feeling in the fingers of that hand. She also described a "burning sensation in the back between the shoulder blades." Soon after the onset of these symptoms she suddenly developed a

choking sensation that was never explained to her satisfaction. Her physician said she had "neuritis." Another said she had "heart trouble and bad nerves," while two cardiologists insisted that there was nothing seriously wrong with her cardiovascular system.

Physical examination revealed moderate limitation of motion in the neck with crepitus in the shoulders and knees. The sedimentation rate was but slightly elevated. Her heart was entirely negative on physical examination and fluoroscopy. The electrocardiogram showed some splitting of the QRS complexes—a finding consistent with mild changes in the myocardium. An x-ray of the cervical spine, however, showed moderately advanced osteoarthritic changes about the bodies of the lower cervical vertebrae. She improved markedly after reassurance and the application of heat to the cervical spine given over a period of six weeks. When last seen, five years later, she stated that she had remained entirely free of symptoms.

Many of these cases of pain in the left side of the chest are dismissed with a diagnosis of "No evidence of cardiovascular disease"; and the statement is often made that "no doubt, there is a large psychoneurotic element in this case." Our own impression is that a good proportion of such patients, if studied carefully with x-ray pictures, will prove to have an arthritis in the cervical spine.

Other Symptoms and Signs of Radiculitis

It has been pointed out that sensory nerves and voluntary muscles are not the only structures that can be affected by this process. A case is cited in the literature⁵ in which there were signs of irritation of the phrenic nerve during an acute flare-up of arthritic symptoms in the cervical spine (persistent hiccough for a period of six weeks). In addition, there are two references^{29,47} to a unilateral Horner's syndrome, which indicates that at times even the cervical sympathetic may become involved in this diffuse process. Nachlas²⁹ has shown that this phenomenon may result from pressure on nerve fibers originating in the region of the first dorsal vertebra. He states that certain nerves—the white rami communicantes—arising from the lower cervical and upper dorsal cord "pass through the cephalic portion of the sympathetic system and assist in the control of the eye muscles."

Conclusion

In general, it may be said that our experience parallels that of Bisgard,⁵ who reached

this conclusion: "Radiculitis may involve any group of nerve fibers contained in any nerve root—motor, sensory, or sympathetic—

and the symptoms—unilateral or bilateral—may reflect evidence of irritation or loss of function—either partial or complete."

Postgraduate Series on War Surgery—Nassau County

To members of the Nassau County Medical Society went the following letter on January 7:

Dear Doctor: The war emergency has produced numerous requests from our members for postgraduate education opportunities in the field of military medicine with particular reference to civilian casualties. Because of the crowded condition of the medical calendar, it has not been possible to arrange a series of lectures as requested without interfering with something else already scheduled. Hence we have reluctantly decided that we shall be forced to postpone or abandon our scheduled postgraduate education series and substitute a new series on war medicine.

Through the assistance of the Nassau Surgical Society, the medical authorities at Mitchel Field, and the cooperation of the several groups concerned with our regular postgraduate program, we are able to announce the following:

Postgraduate Series on War Surgery*

January 12, 1942	Mercy Hospital	Treatment of Shock	Eric Ponder, M.D.
January 19, 1942	Nassau Hospital		
January 26, 1942	Mercy Hospital	Treatment of Gas Cases	Maj. R. E. Lee, M.D., U. S. A.
February 2, 1942	Nassau Hospital		
February 9, 1942	Mercy Hospital	Treatment of Minor Injuries	K. T. Young, M.D.
February 16, 1942	Nassau Hospital		
February 23, 1942	Mercy Hospital	First Aid Treatment of	O. C. Hudson, M.D.
March 2, 1942	Nassau Hospital	Fractures	
March 9, 1942	Mercy Hospital	Treatment of Burns	A. S. Warinner, M.D.
March 16, 1942	Nassau Hospital		
March 23, 1942	Mercy Hospital	Correlation of Treatment	B. W. Seaman, M.D.
March 30, 1942	Nassau Hospital	from First Aid Through Permanent Disposition of Cases	

All Sessions at 4 P.M.

Please note that each of the scheduled lectures will be given twice. It is hoped that as many as possible will attend the first lecture on each subject at Mercy Hospital, thus reserving the smaller auditorium at Nassau Hospital for those members who find it impossible to attend the Mercy Hospital session. In this way there should be room for all who wish to attend.

To conserve funds we shall not send out individual notices of these meetings. Please make note of them in your engagement book and keep this notice for future reference.

Sincerely,

C. W. MARTIN, M.D., *President*

**Nearly 300 doctors and dentists heard the lectures on January 12 and 19.—Editor*

POSTGRADUATE COURSES

The second semester of postgraduate courses will be offered at the Mount Sinai Hospital from February 2 through March 28. These courses, in Bacteriology, Cardiology, Gynecology, General Medicine, Medical Statistics, Neurology, Ophthalmology, Pathology, Pediatrics, and Radiology, are given in affiliation with Columbia University.

Application for courses should be made to the Secretary for Medical Instruction at the Mount Sinai Hospital, New York City, with the exception of courses in Radiology, for which application should be made to the College of Physicians and Surgeons.

NUTRITION PROJECTS IN NEW YORK

More than fifty-five long-range projects designed to raise dietary standards were inaugurated in the state during the Nutrition Fortnight, November 20 to December 3, 1941, according to Dr. Elizabeth M. Gardiner, chairman of the New York State Nutrition Committee. Every cooperating county organization engaged in some form of activity, and the projects begun will be continued as part of the nationwide program to improve nutrition. In thirty-five different areas in the state, for example, local groups are working on school lunch programs. In some cases this will be the first time that hot noonday meals will be made available in schools.

Special Article

MEDICINE MARCHES ON

BERNARD L. SHIENTAG, LL.D., New York City

IT MAY serve a useful purpose, although on the face of it somewhat of a presumption, for a layman to tell how he feels about the progress and the future of medicine. I do this as one with a deep interest in medical problems, one of a group that is growing in size and in understanding largely because of the splendid educational activities of the medical associations of the country.

Long before the first World War, George Gissing, a gifted English writer, said: "I hate and fear 'science' because of my conviction that, for long to come if not for ever, it will be the remorseless enemy of mankind. I see it destroying all simplicity and gentleness of life, all the beauty of the world; I see it restoring barbarism under a mask of civilization; I see it darkening men's minds and hardening their hearts; I see it bringing a time of vast conflicts which will pale into insignificance 'the thousand wars of old' and as likely as not, will overwhelm all the laborious advances of mankind in blood-drenched chaos."

Gissing wrote as one inspired, but what he said was only true in part. For one thing, he confused advance in science with man's use of that advance. The medical profession, through the centuries, has demonstrated that the most remarkable and revolutionary advances in science can be and have been used to promote human betterment and welfare. You have made the body of man "the temple of your miracles." The doctor is the embodiment of the true spirit of democracy. In his every daily task he recognizes the supreme dignity and worth of the individual in the eyes of man, as well as before God. The story of his heroism and of the supreme sacrifice he has made for the advancement of science and for the relief of suffering humanity goes to make up the most glorious and inspiring chapters in medical history.

What a remarkable achievement has been yours! The control of epidemic diseases, smallpox, typhoid, typhus, cholera, and yellow fever resulted not alone in prolonging

human life but in dispelling fear and giving rise to a feeling of hope and confidence. Think of the great saving in life resulting from the discoveries in bacteriology. These led to antiseptics and then asepsis and, together with the introduction and development of anesthesia, widened the scope of surgical intervention, particularly to the viscera of the abdomen and chest, and made for the relative safety of modern surgery with its emphasis on the preparatory treatment of the patient and postoperative care.

There came the discovery and the ever expanding use of the x-ray and technics in connection therewith for diagnostic and therapeutic purposes, the improvement of the microscope, and the discovery of radium. There was the remarkable development of intracranial surgery and the surgery of the nervous system and the use of the encephalogram in connection therewith. There was the ascertainment of the means of treating and controlling syphilis, with the growing, but as yet inadequate and often timid, attempts to cope with that problem. There was the more humane and scientific treatment of the mentally afflicted, with fever and shock therapy offering some hope to the parietic and a faint glimmer of comfort to the schizophrenic.

As we survey the field we find the great advances in gynecology, the control of puerperal fever, and the reduction of the maternity death rate although not to the extent warranted by present medical knowledge. There have been the amazing and almost incredible reductions in the infant mortality rate through control of the diseases of children—what we laymen called summer complaint—the effective control of diphtheria, including susceptibility, prevention, and cure; and the safer and more adequate treatment of scarlet fever, measles, and whooping cough.

More than twenty-five years ago Osler said: "Metabolic therapy represents one of the greatest triumphs of science," and he gave the demonstration of insufficiency of the thyroid gland as a brilliant example of experimental inquiry. Since then, vast vistas have been opened in the field of endocrine

Read at the meeting of the Medical Society of the County of New York, October 23, 1941.

Justice of the Supreme Court of the State of New York, formerly industrial commissioner, New York State Department of Labor.

disorders, in dietetics with its vitamins, and in the domain of allergy. There was the gigantic extension of the public health and sanitation services, and there was Herman Biggs with his pronouncement that "public health, within natural limits, is a purchasable commodity." All these are but an attempt to present in broad strokes a picture of medicine's miraculous contributions to humanity.

Let us consider a few concrete illustrations. In 1908 Welch said (I quote from the interesting biography by the Flexners just published): "At least one-half of the existing sickness and mortality from tuberculosis could be prevented within the next two decades by the application of rational and entirely practicable measures." And the Flexners point out that passing years proved this wild-sounding statement not wild at all.

The figures of the Health Department of the City of New York show that the mortality from tuberculosis (of all kinds) in 1908 was 227.2 per one hundred thousand; in 1933, 64.4; and in 1940, 48.6—a remarkable decrease far beyond that envisaged by Dr. Welch.

In a memorable address by Osler on "The Treatment of Disease," delivered before the Ontario Medical Association in June, 1909, that great physician said: "As our knowledge of the pancreatic function and carbohydrate metabolism becomes more accurate, we shall probably be able to place the treatment of diabetes on a sure foundation." Twelve years later came extracts of insulin from the pancreas.

In that same address Osler said: "There are those among us who will live to see a true treatment of pneumonia; we are beginning to learn the conditions of its prevalence; it may yet come within the list of preventable diseases and let us hope that before long we may be able to cope with the products of the pneumococcus itself. . . . It is not likely," he continued, "that the great masters from Galen to Grisolle lost a larger number of cases than we do." Since Osler spoke there have been "flashes of light in the darkness." Now, medicine has offered a real ray of hope to those afflicted with this dread disease. By resort to serums and especially by the use of sulfanilamide and its derivative, sulfapyridine, there has been an amazing reduction in the mortality rate from this disease, and there has even been a substantial increase reported in the number of recoveries from meningitis of streptococci and pneumococci

origin, heretofore regarded as almost invariably fatal.

Perhaps this statement will complete the broad picture of medicine's great accomplishments. In 1900 the death rate in New York City was 20.6 per thousand; in 1940 it was 10.2; in 1938 it had reached the low of 10 per thousand. In 1860 approximately 9 per cent of the population of this country was 50 years or over; in 1932 it was 16 per cent. In New York City in 1900, 15.9 per cent of the population was 45 years or over; in 1940 it was 27.3 per cent. The life expectancy of newborn babies has been greatly extended. In 1901 in this country, an average American-born white girl baby could expect to live 51.1 years; in 1938 that life expectancy had increased to 66.2 years. Now, it is true that this increase in life expectancy has not been accomplished by medicine alone; improvements in sanitation, in water supply, in housing, in education, and in living and working conditions have had a good deal to do with it, but it all centered around the advances in medical science.

While scientific medicine was making these remarkable advances, the philanthropic or voluntary hospitals and their dispensaries (later called outpatient departments) grew rapidly in scope and in variety of service, though they differed in their methods of charges for treatment to those who were able to pay something but could not afford private medical care. In the course of time the hospital has become the center of the medical care and treatment of all groups in the community, rich and poor; medical education for students and for postgraduates has been built up around the hospital, and it is the center of medical research and investigation. The hospital has been the prime factor in the great improvement in the methods and scope of medical instruction, so that today, of all professional men, the doctor is by far the best educated.

In 1909 Osler, after referring to the magnificent progress of medicine, said: "But the best of human effort is flecked and stained with weakness and even the casual observer may note dark shadows in the bright picture." Some of the shadows noted at that time have since been lightened and even completely removed. There is every reason to believe that what today are dark spots on the fabric of medicine will be cleared up within the next quarter of a century. There will be many more "flashes of light in the darkness" during the coming years, and they will come

as the fruition of painstaking, scientific research, some of which is now under way. Medicine will continue to march on triumphantly.

What to a layman appear to be the directions that medicine is likely to take in the future? Generally speaking, there will be an increased emphasis on prevention, on public health work, and on the early recognition of those changes in function which are called disease.

The combat will center around the diseases of adulthood, cancer, and the diseases of the circulatory system, manifested by heart disease, nephritis, and cerebral disorder and hemorrhage.

Attention will be focused on maternity and prenatal care, with a view to bringing about a greater reduction in the maternity death rate and in the mortality rate of infants under one month. We look to the future with a confidence, born of urgent hope, that much greater progress will be made in the prevention and treatment of mental diseases, including the establishment at an early date of a new type of hospital or nursing home—a sort of “preventorium” for incipient mental ailments—to which appropriate cases may be sent without court, or even without voluntary, commitment.

The health of children and of adolescents during their period of education will be of increasing concern, to discover susceptibility to disease, mental as well as physical; to take appropriate measures to prevent its outbreak; and to remedy physical defects before they have had a chance to do much damage.

Greater success will attend efforts made for the preservation of the function of hearing. There will be a determined, courageous fight against syphilis and other venereal diseases—their prevention, treatment, and cure. There will be more attention paid to the problems of metabolism, of nutrition, and of allergy. Medicine will pierce the veil that now obscures the solution of so many of the fascinating and puzzling questions of immunization.

The resources of medicine and its allied sciences will be devoted to an intensified combat on those formidable enemies of man—the viruses and other infectious agents—looking toward the discovery of their mystery and “the suppression of their evil sway.” We recall with dread the epidemics of infantile paralysis and how in the year 1918–1919 influenza claimed more victims than the first World War, which lasted four years.

Surgery will continue its remarkable advance and there will be new miracles of surgical intervention.

To the lay mind, there is a real question as to whether specialism has not developed beyond the actual needs of the profession and of the public. There will continue to be specialists, for to them a good deal of progress in medicine is due. But they will be real specialists, men of intensive training and of outstanding skill in their respective fields. The organized medical profession will continue, and make more effective, the fine work it is doing in the licensure of specialists, and there will be fewer of those self-styled, half-baked specialists who plague us today. I hope—and this, in candor, is more of a hope than an expectation—that medicine will be put back into the hands of the well-trained general practitioner, with group laboratory facilities at his command for diagnostic research and to some extent therapeutic treatment, with reference, of course, to specialists when the nature of the case requires it.

There will be a more concerted movement on the part of the medical profession as a whole for the elimination of social conditions that breed disease. To use the language of the well-known Commission on Education: “Sound medical care requires that the physician understand the importance and the influence of social, economic, and psychological factors, as they contribute to the causation, treatment, and prevention of disease in the individual.” In short, the next era will be one of increasing medical humanism, an era in which not only will human life be prolonged but medicine will help to make that life healthier, happier, and more productive.

Reference must be made to one of the most important problems that medicine has to face in the future—that of medical costs, particularly as they affect the millions of our people in the low-income groups. Dr. Osler in one of his addresses observed: “Of the three factors in practice, heart, head and pocket, to our credit be it said, the first named is the most potent.” The entire history of medical practice, through the ages, demonstrates the truth of this assertion. There has been, and there now is, no more unselfish, self-sacrificing, humanitarian group in the community than the members of the medical profession taken as a whole. The doctor is the symbol of service to society.

There has been a most desirable widening of the scope of governmental activities along health lines—the care in public hospitals of

the mentally afflicted, the tubercular, the sick and disabled war veterans, crippled children, and the victims of venereal disease. Public agencies, such as maternity, prenatal, and child health clinics, have been established in constantly increasing numbers. The government is paying private physicians for the medical treatment of the blind and those who are on relief.

There has also been a great and beneficial extension of social welfare legislation which has resulted in improving living and working conditions—the Factory and Child Labor Laws, the Workmen's Compensation Law, Minimum Wages, Old Age Security, and Unemployment Insurance. Despite all this, there are still millions of low-paid wage earners to whom serious illness, especially if it requires hospitalization, comes as a great catastrophe. It has been urged that we should complete our system of social security, which up to the present has been approved in principle by all of the political parties, so as to include a plan of compulsory health insurance for low-paid wage earners, based upon contributions by the workers, their employers, and the state.

The medical profession is strongly opposed to any such plan, fearing that it would tend to destroy the free and independent practice of medicine. In old age and unemployment insurance there is no element of service to be considered; only cash benefits are involved. In any system of compulsory health insurance the great emphasis is placed not on the cash benefits for loss of wages due to illness but on the furnishing of adequate medical care and treatment. Doctors have done so well, however, in preventing, treating, and conquering disease, and they have been so successful in prolonging human life and making it more enjoyable while it lasts, that many of us who have been zealous in advocating social security legislation have been reluctant to join in the support of a plan for compulsory health insurance which, for its successful administration, depends almost entirely upon the cooperation and support of the medical profession.

Nevertheless, the situation as I see it comes down to this: Either there is likely to be a system of compulsory health insurance for the low-income groups, with the best provisions that can be devised thereunder to maintain proper standards of medical service by private physicians, or there will have to be developed, within the medical profession, adequate plans for voluntary group health

insurance for such low-wage employees which will at least meet their most urgent needs for medical treatment and care during serious illness requiring hospitalization. It is my conviction that the second alternative is today the desirable one. The most significant and most heartening development along this line was announced recently by the Associated Hospital Service of New York. It provides a new medical and hospital insurance plan, known as the Community Ward Service plan, for hospital care and medical treatment in the hospital for employed men and women of limited incomes and their families at premiums ranging from \$12 to \$27 a year.

This plan does not purport to solve the entire problem; it does not deal with the ordinary cases of illness necessitating visits to the doctor at his office or by the doctor to the home. But it does deal with what, to the low-paid worker, are catastrophic episodes in his individual and family life and is, thus, a most important and significant step with great future possibilities. As a layman, I cannot presume, without the most thorough study at any rate, to pass on the actuarial or medical soundness of the plan. There must, of necessity, be a certain amount of experimentation, of reliance on the method of trial and error. Defects and shortcomings, as they appear, may be corrected, for the plan is under the supervision and control of a group of physicians, devoted to the high ideals and fine traditions of the medical profession and responsive to its needs. Experience under this plan will be watched with keen interest all over the country. It is to be hoped that the medical profession and all those concerned with problems of health will give the plan their friendly support and cooperation.

Any plan of health insurance, whether developed from within the profession or without, must leave unimpaired the personal responsibility of the trained physician in the case and treatment of the sick, preserve the independence and initiative of the private physician and his personal relationship to his patient, afford a real freedom of choice of physicians by the sick, safeguard the quality of the medical service and the economic position of the doctor, and emphasize the importance of prevention and research. The organized medical societies and their views, or those of representative bodies of physicians of standing, should be recognized in any such plan.

There should be utilized the experience under the New York State Workmen's Compensation Law, where the quality of medical

service and the position of the doctors have been materially improved in consequence of amendments giving to the organized medical societies a certain measure of control and a corresponding degree of responsibility.

I know of no better way to describe the mission of the doctor in the modern world than by using the beautiful and eloquent words of a great leader of the medical profession on the other side of the Atlantic. I refer to the concluding remarks of Lord Moynihan in an address to the members of his profession when he was President of the Royal College of Surgeons of England:

"To give courage to those who need it, to restore desire for life to those who have

abandoned it, with our skill to heal disease or check its course—this is our great privilege. Ours are not the mild concerns of ordinary life. We who, like the Happy Warrior, are 'doomed to go in company with Pain and Fear and Bloodshed,' have a higher mission than other men, and it is for us so to labour that we may prove not unworthy."

The medical profession will, I am sure, carry on that high mission in a manner worthy of its fine traditions in a world in which there will be an end to man's inhumanity to man, a world in which we shall be able to "pause in living to enjoy life," a world in which peace with freedom and justice and good will shall prevail among all nations.

EXAMINATIONS—AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The general oral and pathologic examinations (Part II) for all candidates (Groups A and B) will be conducted at Atlantic City, New Jersey, by the entire Board, prior to the opening of the annual meeting of the American Medical Association in Atlantic City, on June 8, 1942.

Application for admission to Group A, Part II, examinations must be on file in the Secretary's Office not later than March 1, 1942. It will greatly facilitate the work of the Board if applications are filed as far as possible in advance of the closing date for their receipt.

Formal notice of the time and place of these examinations will be sent each candidate several weeks in advance of the examination dates.

Candidates for re-examination in Part II must make written application to the Secretary's Office before April 15, 1942.

As previously announced in the Board booklet, this fiscal year (1941-1942) of the Board marks the close of the two groups of classification of applicants for examination. Thereafter, the Board will have only one classification of candidates, and all will be required to take the Part I examinations.

The Board requests that all prospective candidates who plan to submit applications in the near future request and use the new application form which has this year been inaugurated by the Board. The Secretary will be glad to furnish these forms upon request, together with information regarding Board requirements. Address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

DOCTORS URGED TO WRITE PRESCRIPTIONS

Dr. Frederick Lascoff, assistant professor of pharmacy, Columbia College of Pharmacy, recently decried the effect of high-pressure salesmen in convincing physicians that proprietary medicines are better compounded and cheaper than those prepared by ethical pharmacists. He pointed out that the prescription proprietary of today becomes the patent medicine of tomorrow, and that the prescription should be written to suit the needs of the patient rather than compelling the patient to accommodate himself to the medicine.

He mentioned many medicines that might be prescribed at a considerably lesser cost to the patient than the equivalent proprietary remedy—such as cod-liver oil ointment, phenobarbital instead of veronal, pentobarbital sodium instead of nembutal, and U. S. P. digitalis instead of a trade name digitalis. He recognized that the manufacturers have done a great deal of good by their research work but stated that he felt the manufacturers have gone beyond their field in attempting to take over the field of retail pharmacy.

Dr. Lascoff urged physicians to write prescriptions instead of merely giving the name of a drug verbally. To demonstrate the difficulty that the pharmacist has in pleasing all his physician friends because of their addiction to proprietary prescribing, Dr. Lascoff pointed out that there are 87 different preparations of digitalis and 111 different barbituric acid preparations which the pharmacist must carry in stock.—*Westchester Medical Bulletin*

Two psychoanalysts met: Said one to the other—"You feel fine. How do I feel?"

—J.A.M.A.

"How come you were born in Ireland?"
"Well, you see, I wanted to be near my mother."

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the College and Hospital, students and visitors. The next report will appear in the March 1 issue and will concern "Treatment of Some Intestinal Infestations."

Treatment with Sulfonamide Drugs

DR. C. H. WHEELER: In a therapeutic conference held about a year ago and printed in the *NEW YORK STATE JOURNAL OF MEDICINE* for May, 1941, we reviewed the subject of treatment with the sulfonamide drugs. At that time we discussed sulfanilamide, sulfapyridine, sulfathiazole, and sulfadiazine—their relative merits, specificities, and dangers. Many papers have appeared since and new sulfonamide drugs have been introduced. Today, we will attempt to bring the subject up to date. Dr. Modell will discuss the pharmacologic aspects of the subject.

DR. WALTER MODELL: Actually, little has been published to broaden the pharmacologic concepts of the sulfonamide derivatives, but new drugs have been added to the list and therefore it becomes necessary to modernize the order in which one would place these drugs with respect to their different pharmacologic properties.

In choosing a sulfonamide derivative, the clinical characteristics of specificity and ease of administration must be considered. In addition, there are the pharmacologic features that also must be taken into account—the rapidity of absorption and elimination, the degree of acetylation, and the toxicity. By balancing the pharmacologic characteristics against the clinical effectiveness and urgency, one determines which of a rather large list of drugs today available should be used for a particular patient in a particular situation. A comparison of pharmacologic properties becomes extremely useful if one uses this kind of reasoning in choosing a sulfonamide derivative.

Last year we were fortunate to have one of the earliest discussions of sulfadiazine by Dr. Plummer. At that time sulfaguandine had just made its debut, but there was no opportunity to discuss it. I think it was exactly a day before the conference that a paper from the Mayo Clinic presented promin, and since

then another sulfonamide derivative, sulfacetamide, which is not really a "brand" new drug, has been introduced by way of vigorous advertising literature.

The absorption of most of these drugs from the gastrointestinal tract is rather rapid. Sulfanilamide and sulfadiazine are about equal in the rate of absorption, and in three to four hours a peak of blood concentration is reached after a single oral dose. Sulfathiazole is almost as rapidly absorbed; sulfapyridine is much more slowly and much more irregularly absorbed. The sodium salts of these drugs appear to be more rapidly absorbed from the gastrointestinal tract. Sulfaguandine is, on the other hand, poorly absorbed from the gastrointestinal tract. By far the greatest part passes with the fecal mass and out of the body without entering the blood stream. If a dose of sulfaguandine of 0.1 Gm. per kilogram is given every twelve hours, the blood level rarely goes up beyond 3 or 4 mg. per hundred cubic centimeters, and it is this property of poor absorption of sulfaguandine which gives it theoretic usefulness in intestinal infections. It is well to remember, however, that while a high concentration of it is maintained in the feces, it is absorbed in part; it is, therefore, not without systemic effects and dangers.

As soon as any of the sulfonamide derivatives are absorbed, they are diluted by the tissues of the body and permeate all the organs, the exudates, transudates, and fluids. Recently, sulfonamide derivatives have been identified in tears, so that no fluid in the body seems to escape the distribution of sulfanilamide. Although this distribution tends to be uniform, some organs such as bone and fat contain appreciably less sulfanilamide than others. More important is the fact that there appears to be some barrier to the passage of sulfonamides to the cerebral spinal fluid, so that the concentration of any sulfonamide derivative in cerebrospinal fluid is never equal to that found

in the blood stream. In the case of sulfanilamide and sulfapyridine it is generally about two-thirds of the concentration in the blood stream; of sulfathiazole, it is much less, sometimes as little as one-third. In the case of sulfadiazine it is two-thirds, and sometimes even as much as 80 per cent, of the concentration found in the blood stream.

Almost immediately after the sulfonamide derivatives enter the blood stream acetylation begins, a process that takes place primarily in the liver and perhaps to some extent in the spleen. Acetylation is exceedingly important, because by acetylation these drugs lose their therapeutic effectiveness, become somewhat more toxic, and become so much less soluble that if the acetylated drugs are sufficiently concentrated they may precipitate out of the urine into the kidney tubules or urinary tract and cause urinary disturbances.

Sulfadiazine is perhaps the least acetylated of all the sulfonamide derivatives. About 10 or 15 per cent of sulfadiazine is usually found in the acetylated form. Sulfanilamide runs pretty close to this. In the case of sulfathiazole it is perhaps a little more; about 25 per cent of the sulfathiazole is acetylated. For sulfapyridine it is sometimes 50 per cent or more. About 50 per cent of sulfaguanidine is acetylated, but the blood concentration of sulfaguanidine is usually so low that the degree of acetylation is not particularly important.

Sulfacetamide presents a unique feature in acetylation. Sulfacetamide is a sulfonamide derivative that is acetylated in the laboratory. Acetylation of the sulfonamide group as a whole takes place *in vivo* at the amide (NH_2) group. If the sulfanilamide is acetylated *in vitro* at the sulfonamide group (SO_2NH_2), it is intimated by the manufacturers of sulfacetamide that further acetylation *in vivo* is prevented. Sulfacetamide is such a drug. It is relatively nontoxic and is effective against a group of infections, more especially those of the urinary tract. It would be desirable to have a sulfonamide derivative that was not acetylated. It would give the drug a unique and valuable property. What actually happens in the body with sulfacetamide is that a considerable portion of this drug has the laboratory attached acetyl group removed, converting the drug back to sulfanilamide which in turn is acetylated by the liver in exactly the same manner as usual. What finally is present in the body after the use of sulfacetamide is a mixture of sulfacetamide, sulfanilamide, and acetyl-sulfanilamide.

It should be mentioned that the acetylated sulfonamide compounds are more soluble in alkaline than in acid or neutral mediums, and several studies have been published which indicate that the precipitation of crystals of the acetylated form in the urine may be prevented to a considerable degree by the administration of enough sodium bicarbonate to make the urine alkaline.

The sulfonamide drugs vary in their rate of elimination. Perhaps the most rapidly eliminated is sulfathiazole and in descending order sulfanilamide, sulfapyridine and, finally, sulfadiazine, which is perhaps the slowest. For that reason, after a single dose of sulfadiazine, a high blood concentration is maintained for a long period of time.

I should like to separate the toxic effects into two categories: the sensitivities, which cause disturbances, and symptoms which are mainly clinical features seen only in humans and the toxicity demonstrable in animals.

All derivatives of sulfanilamide have been introduced with the claim that they are less toxic and that the lethal dose is higher than that of sulfanilamide. That has been said of sulfapyridine and sulfathiazole, but in the end it has been proved that sulfanilamide is still about the least toxic of the whole group when considered in terms of the lethal dose for animals. But animal experiments usually do not indicate the amount of distress a human is likely to suffer after taking one of these drugs. Sulfanilamide and sulfadiazine are about equally toxic for experimental animals, sulfathiazole comes next in the list and, finally, sulfapyridine, which is the most toxic of the group.

There is still a great deal of debate on the mode of action of these drugs. There are a number of theories that have been presented, but we do not have time to discuss them here, and certainly there is no positive proof as to which type of action is the most important. The trend of opinion is in favor of an antienzymatic effect, which in turn interferes with bacterial metabolism.

A new and interesting phase of this subject is the discovery that para-aminobenzoic acid, which is a constituent of the vitamin B complex, prevents the action of sulfanilamide *in vitro* and *in vivo*, both in the body and in the urine. As yet this has not contributed greatly to our understanding of the action of the sulfonamide group. Para-aminobenzoic acid, which is chemically similar to sulfanilamide, is said to be able to displace it and, therefore, prevent its antienzymatic action. It is im-

portant that although the antibacterial action of a sulfonamide can be prevented by para-aminobenzoic acid this neutralization of action does not extend to toxic effects, cyanosis, vomiting, nausea, and the whole list of symptoms that appear just as frequently whether or not para-aminobenzoic acid is used.

Just a word about promin. It is not really a sulfonamide but is a diaminodiphenylsulfone derivative. It was introduced because of some experimental evidence that it was of value in preventing tuberculosis in animals. Its clinical value is now under investigation and is far from proved.

DR. WHEELER: Dr. Plummer, will you continue the discussion?

DR. NORMAN PLUMMER: The subject of sulfonamide therapy has expanded to such great dimensions during the last few years that one can really only touch on a few highlights of it.

A year ago at this conference I related the story of the development of sulfonamide therapy up to the time when sulfadiazine and sulfaguanidine had had their earliest clinical trials. The preliminary experimental studies indicated that each had advantages over the earlier sulfonamides, and the first clinical trials as reported here were also favorable for each. The past year has shown that our enthusiasm for sulfadiazine was well founded but that the same was not true for sulfaguanidine. Sulfadiazine, with extensive usage, has been found to have the advantages originally described for it.

At a symposium on sulfonamide therapy recently held in Albany, it was the consensus that sulfadiazine was the least toxic and the most useful of all of the sulfonamide drugs. It was intimated strongly that sulfadiazine would displace the others of the group as the drug of choice in every infection responding to sulfadiazine. At this same symposium there was little said about sulfaguanidine. Dr. Marshall, on direct questioning, stated that he believed the value of sulfaguanidine had been proved only in certain bacillary dysenteries. He favored sulfadiazine or sulfathiazole over sulfaguanidine for prophylactic use in surgery of the intestinal tract. He emphasized the importance of observing all of the precautions against toxic reactions.

At the New York Hospital and at Bellevue Hospital we have reviewed the records of 457 patients who received 10 Gm. or more of sulfadiazine for manifestations of toxicity. In this series gross hematuria and renal colic were the most serious reactions and occurred in 7

cases, subsiding promptly in each on cessation of sulfadiazine therapy and at no time causing anuria. Drug rash with fever was the only other reaction of significance, and this occurred in 10 cases. There was no case of hemolytic anemia or agranulocytosis but, since making this review, 1 patient died of acute thrombocytopenia, which developed while receiving sulfadiazine. In 457 patients a mild leukopenia developed five times and an anemia once. There was stomatitis in 1 patient and temporary partial deafness in another. Nausea and vomiting were almost negligible.

At the Albany symposium the physicians were canvassed for information regarding serious toxic reactions following the use of sulfadiazine. There was an experience with several thousand cases. No instance of severe hemolytic anemia and none of toxic hepatitis was known to have occurred. Dr. Finland reported 1 case of agranulocytosis following the administration of sulfadiazine and 1 case of anuria, the latter after a gross misuse of the drug. There was no other case of thrombocytopenia than the one we described.

During the past year a great deal has been learned about the modes of administration of the sulfonamide preparations. While there are some striking differences between sulfapyridine, sulfathiazole, and sulfadiazine, many of their chemical and pharmacologic properties are the same. All three of these drugs are poorly soluble in water, although they are well absorbed from the gastrointestinal tract. The sodium salt of each of these drugs is highly soluble, so that solutions up to 50 per cent or even higher can be prepared, but these are highly alkaline and, when applied to the mucous membranes or denuded tissues, they are irritating. Soon after the introduction of sulfapyridine, it was found that because of its low solubility it could not easily be administered parenterally. When sodium sulfapyridine was described, pharmacologists strongly advised against its use because of its high alkaline reaction. They believed that severe tissue damage would be produced. Cautiously, dilute solutions of sodium sulfapyridine were tried intravenously, and after a time this became an accepted method of administration.

The most recent experience has been with sodium sulfadiazine. This sodium salt is soluble to the extent of approximately fifty parts in one hundred parts of water and is slightly less alkaline than the sulfapyridine salt. It has been recommended that the so-

dium sulfonamide drugs be administered in 5 per cent solution in sterile distilled water. During the past year, here and at Bellevue, we have administered intravenously routinely 25 per cent sodium sulfadiazine in distilled water. This has been a greatly simplified procedure because we have had the preparation in sterile ampules and have required only a 10- or 20-cc. syringe and a needle. We have used a small gauge needle and have made the injections slowly. Up to the present there have been no local or general reactions that would contraindicate this method.

By intravenous injection it is possible to establish immediately in the blood stream the desired concentration of drug. Having proved this to be a safe and practical method, there is found a large group of the more seriously ill patients who will benefit by the intravenous therapy, at least at the beginning of treatment. Furthermore, there is good clinical evidence that the organisms are more susceptible to the sulfonamide drugs when a proper concentration is obtained quickly rather than gradually. On this basis it may be sound therapeutics to initiate sulfonamide therapy always by intravenous injection and to maintain it by oral administration.

The sodium salts, in spite of their high alkalinity, have been administered through about every possible channel. They have been given orally, rectally, subcutaneously, intramuscularly, intrapleurally, intraperitoneally, intraspinally and, more recently, in ointments, lotions, and sprays applied locally to the skin and mucous membranes. The relative value of each of these methods has not been fully established, and there remains a definite question as to whether the local treatment ever has any advantage over internal administration. The value of local use may depend entirely upon the absorption into the blood.

A few remarks about the various less common methods of administering the sulfonamide drugs seems appropriate. During the past year Dr. Wheeler and I have studied 57 patients with a variety of infections who received sodium sulfadiazine orally rather than sulfadiazine. These patients, so far as we could ascertain, responded in the same manner as did patients treated with the usual sulfadiazine medication. Furthermore, we were unable to recognize any differences in toxicity, and there was no evidence of local irritation of the stomach or intestine such as the occurrence of nausea or vomiting. We did discover the same pharmacologic advantages

that had already been described following sodium sulfapyridine orally. The concentration of sulfadiazine in the blood rises more rapidly and to a definitely higher level following the sodium salt than it does after sulfadiazine is given in equal dosage. It would seem from this finding that the sodium preparation is a superior one even for oral usage.

Taplin, Jacox, and Howland demonstrated that 3.0 to 7.0 Gm. of sodium sulfapyridine could be administered safely and without additional discomfort in the usual saline hypodermoclyses. Recently, in some clinics sodium sulfadiazine has been administered in the same manner with satisfactory results. It has been used in this institution on a few occasions. This affords the most convenient and effective way of administering the drug in an occasional case. However, when parenteral treatment is required, the intravenous route is most often preferred.

Following rectal instillation, all of the sulfonamide drugs are absorbed slowly. However, this applies to the sodium salts to a lesser degree. There seems to be little or no indication for the rectal use of the sulfonamide drugs, and this mode is to be discouraged.

It is a question which of the preparations, the insoluble base or the strongly alkaline sodium salt, one would consider less hazardous for intrapleural, particularly intraperitoneal and intraspinal, administration. I have a suspicion that some of the enthusiasm that has followed this radical therapeutics has arisen from having "got away with the procedure" rather than from a striking clinical result. But there may be something gained from knowing that the drug can be administered through these channels. The rationale is not strong for injecting the sulfonamide drugs directly into the body cavities because high levels do not seem to be advantageous and the necessary levels can be obtained so much more satisfactorily by oral or parenteral administration.

This brings up the question of the value of the sulfonamides for local application. This could be a treatise in itself, and I have time for only a few of the more pertinent observations regarding it. Sulfanilamide and, recently, sulfadiazine have been used locally in abdominal surgery, and there have been enthusiastic reports on these cases. Most of these patients, however, were receiving the drugs parenterally or orally in addition, so that the value of the local applications cannot be accurately estimated. For myself, in these cases, I should feel a great deal safer with the

systemic treatment than with the local. Another factor that makes evaluation difficult is that whenever the drug is applied locally there is always absorption, sometimes with an appreciable blood concentration.

At Bellevue Hospital we have seen the treatment of a number of patients with empyema with the various sulfonamides intrapleurally. My own impression regarding these cases is that even though some of them had high concentrations of the drug in the pleural fluid there was no alteration in the bacterial flora of the fluid and no change in the course of the disease. On the other hand, there was no particular ill effect from using the drug in this manner. Sodium sulfathiazole solution has been used by the otolaryngologists for irrigating infected sinuses. I am sure that all of you are following the controversy concerning the interpretation of the results in these cases. Some nose and throat men, of course, are extremely enthusiastic, and others feel there is nothing to it at all.

Undoubtedly there are two sides to the argument concerning local therapy. We have seen a few cases of burns treated with a preparation of sulfadiazine and triethanolamine. The areas of granulating tissue appear clean and healthy. Compound fractures and various traumatic wounds treated with sulfonamide packs usually appear remarkably free from infection. These cases and others convince one that the sulfonamides have a significant local action. To evaluate it and to define the local and general indications remain one of our important problems.

I want to present one other topic that is even more controversial: the prophylactic use of the sulfonamides. When we were working with such a drug as sulfapyridine, this was not so important, because the toxic reactions were so bothersome, particularly the nausea and vomiting, that no one would use the drug except in case of great necessity. The situation with sulfadiazine is much different. The toxic reactions from it are so uncommon that there is great temptation to use it in minor infections and also as a preventive measure.

Already, with sulfanilamide, important studies have been carried out on the prevention of rheumatic fever in susceptible individuals. Groups of children here in New York City and in Baltimore who already have had one or more attacks of rheumatic fever or one of the related diseases were given sulfanilamide in small dosage daily during the winter and spring months when streptococci

infections occur most frequently. In both groups there was a greatly reduced incidence of rheumatic fever and streptococcal infections as compared with the control groups. In the Baltimore series none of the 55 treated children had a major attack of rheumatic fever, while in the control group 15 cases occurred. The small daily dosage of sulfanilamide produced no recognizable toxic reactions in either study.

In many fields of medicine the prophylactic value of the sulfonamides is being investigated. The following represent a few of them: (1) prevention of scarlet fever and septic sore throat among the contacts of patients with these diseases; (2) prevention of complications of measles and whooping cough; (3) prevention of complications of colds and influenza; (4) prevention of urinary tract infections following catheterization, cystoscopy, and other urologic surgical operations; (5) prevention of sepsis following oral and nose and throat surgery; and (6) prevention of local and general infections developing from operative and traumatic wounds.

Prevention of infection in surgery is probably one of the most important prophylactic uses of these drugs. I am referring here to the administration of sulfonamides by mouth or by vein preoperatively. Their use in appendicitis, particularly when there is a possibility of ruptured appendix and peritonitis, is quite generally practiced. In surgery on the colon or stomach in which peritonitis or a more general infection is a constant danger, these drugs seem to have a real value.

Many thoracic surgeons are using the sulfonamide drugs preoperatively in the more extensive procedure such as thoracoplasty and lobectomy. It is the impression that in addition to preventing infection at the site of the operation the prophylactic use of these drugs greatly reduces the incidence and hazards of postoperative pneumonia. This subject of the use of sulfonamide therapy in surgery is a timely one, and I know that we are going to hear more about this from Dr. Bowers.

Before concluding, I want to say a few words about the results that are being obtained with sulfadiazine in some of the more important diseases, particularly pneumonia.

Sulfadiazine has been given extensive trial in pneumococcal pneumonia, and most encouraging reports on its use have appeared from the services of Flippin in Philadelphia, Finland in Boston, and Dowling in Washington. The fatality rates have been as low or

lower than after any of the other sulfonamide drugs, and the incidence of toxic manifestations has been particularly low.

Drs. Ensworth, Kalkstein, Barefoot, Liebmann, and I have just completed an analysis of the records of 239 patients with pneumococcic pneumonia treated with sulfadiazine at Bellevue Hospital. The fatality rate was 10.9 per cent—7.8 per cent when the twenty-four-hour deaths were excluded. There were only 2 deaths among the 86 patients under 51 years of age—one of these died in less than twenty-four hours after admission. These fatality rates must be near the lowest that it will be possible to obtain. It has been stated that patients no longer die of uncomplicated pneumonia. An analysis of the 26 fatalities in our series treated with sulfadiazine almost completely bears out this statement. This group included 8 patients who died in less than twenty-four hours after admission. It also included 8 with serious cardiac disease; 2 with diabetes; 1 in coma; 1 with nephritis and uremia; 1 with acute lymphogenous leukemia; 1 with myocardial infarction; and 3 patients admitted late who were found to have pneumococcic endocarditis. One wonders if there is a single patient in this list who might have been saved by a theoretically perfect pneumonia therapy. We might select 2 or 3 possible recoveries.

How might they be saved? Serum, perhaps? But such cases are almost always the "late therapies," when theoretically and practically serum has little or no value. Such reasoning does not add to one's optimism over the future of antipneumococcus serum. On the other hand, it does support the important dictum of early diagnosis and early treatment.

The dramatic results following sulfadiazine that I have just reported for pneumonia are being duplicated in other infections such as meningococcic meningitis, gonorrhea, and some of the urologic and surgical conditions. I regret not having time to present the details of these results.

DR. WHEELER: Dr. Bowers will discuss the prophylactic use of the sulfonamide drugs in surgery.

DR. RALPH F. BOWERS: Dr. Plummer has introduced this phase of the subject aptly, but I think to really appreciate the results obtained with this drug you should know something of our experience. Formerly, in abdominal surgery—and that is the type of case in which we have used these drugs—surgeons have made all sorts of efforts to develop "im-

munity" in the peritoneal cavity. They have performed multiple-stage operations; they have given vaccines; they have administered other chemotherapeutic agents into the peritoneum. The literature is replete with the good results obtained, except that they were never perfect.

It occurred to some of us that if the sulfonamides brought about a decrease in the number of mastoid infections following middle-ear disease and have almost taken away from our wards Ludwig's angina, cellulitis of the leg, and many other infections I could mention, then it might be of benefit in abdominal surgery to prevent serious infection.

In the management of seriously infected abdominal lesions, one wishes to eliminate the complications that are responsible for deaths. The most important of these are peritonitis, extensive localized infections, pneumonia, evisceration, or a combination of these terrifying conditions. The mortality in surgery of the colon, for instance, ranged between 20 and 25 per cent due to the above-mentioned complications. About a year and a half ago I began using the sulfonamides prophylactically to prevent or treat the bacteremia or septicemia that may be produced by handling and manipulating an infected organ. Even in so simple a procedure as passing a catheter, bacteremia can be demonstrated in 40 per cent of the patients who experience a chill after the catheterization.

I cannot go into all the types of cases in which we have used these drugs, but I want to mention some of them. In appendicitis, when we feel reasonably sure that we are also dealing with peritonitis, before operating we first give a sulfonamide clysis. At present, we give sodium sulfadiazine intravenously so that when the patient is ready for the operation he has a blood level around 3.5 to 4 mg. per hundred cubic centimeters. This is maintained by the intravenous route of administration. Then, as soon as the patient is able, he takes the drug by mouth. The administration of the drug is continued for a period of about one week. Our results with this method have been gratifying.

The drugs have been used prophylactically in cases of infected tumors of the large bowel, rectum, sigmoid, descending colon, cecum, ascending colon, and stomach, as well as in cases of ulcerative colitis which require resection and in those with particularly severe infection which require colectomy. I do not mean to imply that use of the drugs compensates for "sloppy" surgery. They must be

used as an adjunct to good surgery and not a substitute for it.

In all but a few patients of our present series of 38 the wounds have healed *per primam*. In some cases a mild infection has developed. Simple opening of these has resulted in prompt healing of the wound. There has not been a single case of evisceration, nor have we had an instance of postoperative pneumonia in this group of cases with infected tumors in the abdomen, in which pneumonia has ordinarily been apt to develop and in which the mortality due to infection is high.

I feel so enthusiastic about our results with this method of treatment that at the risk of exaggerating I should say that for these cases the sulfonamides, so far, have provided the only real "immunity" from infection.

DR. WHEELER: The meeting is now open for questions.

DR. JANET TRAVELL: I wonder if Dr. Plummer would briefly outline the dosage plans used with sulfadiazine.

DR. PLUMMER: In the treatment of pneumonia we have decided on 4 Gm. as the initial dose. This is in the adult patient.

DR. TRAVELL: By mouth? By vein, or how?

DR. PLUMMER: The method as we have been using it is 4 Gm. by mouth as the initial dose and then 1 Gm. every four hours by mouth. We usually give a total dosage of about 20 Gm. in the uncomplicated case. This procedure is modified at times to include an initial dose of 2.5 Gm. intravenously.

DR. TRAVELL: When do you stop using the sulfadiazine?

DR. PLUMMER: We believe it is a good plan to continue it for at least twenty-four hours after the temperature has subsided.

DR. MODELL: What blood level of sulfadiazine is considered desirable?

DR. PLUMMER: We do not know what the most desirable blood level is. With the dosage outlined, usually a level of between 8 to 12 mg. per hundred cubic centimeters is reached.

DR. TRAVELL: When you give the sodium sulfadiazine by vein, do you start with an initial dose of 4 Gm.?

DR. PLUMMER: When we give sulfadiazine intravenously, we give 2.5 Gm. We have it made up in ampules of 10 cc. of a 25 per cent solution, which makes it more convenient to give the 2.5 Gm.

DR. TRAVELL: You give the first dose orally at the same time?

DR. PLUMMER: Yes, we give the first oral dose at the same time.

DR. MODELL: Last year we had some unfinished business. When the conference closed we were talking about the status of sulfapyridine and the sulfonamide derivatives in subacute bacterial endocarditis, and we closed the subject on a pessimistic note. Can we change that note today?

DR. WHEELER: Will you make a statement, Dr. Deitrick?

DR. JOHN B. DEITRICK: I can say we have not found the sulfonamide drugs effective in this hospital in the treatment of subacute bacterial endocarditis. We have used it on nearly 50 patients, starting with the sulfanilamide in 1937, then sulfathiazole, then sulfapyridine and sulfadiazine. To my knowledge only 1 is alive of the entire group. I know 38 are dead. Five or 6 left the hospital while the disease was in a definitely progressive state. We have patients in whom a normal temperature results, but in our experience, if the blood cultures are incubated for fifteen or twenty days, the organisms will always be found, although the plates may be negative at ten days. You may not see a colony on the tenth day, but if you subculture and add special mediums they will grow more rapidly.

DR. MODELL: What about the use of heparin?

DR. DEITRICK: The only thing I know that heparin will do is to keep the clot from forming. This is one of the protective mechanisms of the body, because with the fibrin the infection might be warded off. With heparin you prevent fibrin forming around the organism. In this hospital we are not in favor of the use of heparin, but I must admit we do not know enough about it.

DR. HAROLD G. WOLFF: May I ask whether the cerebrospinal fluid determinations of the various drugs take into account the long lag before equilibrium is reached between blood and the spinal fluid? Perhaps hours pass before they approach each other.

In the case of blood sugar in diabetes, it is ten to twenty hours before the spinal fluid level approaches that of the blood. In the case of sulfadiazine would it be two-thirds of that level after equilibrium has been established?

DR. MODELL: Many cerebrospinal fluid determinations were made after eight or ten days of therapy—days after equilibrium had been reached and a constant level maintained in the body—yet the discrepancy between the

level in the cerebrospinal fluid and the blood continued.

DR. WHEELER: Dr. Wolff's point is illustrated in many of our patients in whom several spinal fluid determinations were made in a single day with simultaneous determinations in the blood. Occasionally, at the time of the second lumbar puncture, the cerebrospinal fluid level was higher than the blood level, corresponding to the blood level that was present six or eight hours previously, thus demonstrating a lag.

INTERN: Dr. Plummer mentioned prophylaxis in rheumatic fever. The important point is to prevent the streptococcic infection. Once that had been established no amount of drug is of value. Furthermore, a patient suffering from acute rheumatic fever is not one to whom it is advisable to give sulfanilamide, and frequently such a patient is harmed by the drug. It is a prophylactic to prevent the streptococcic infection. Once a streptococcic infection has been established there is no point in continuing the sulfanilamide.

DR. MODELL: I should like to mention in this connection a patient in a series of children with rheumatic heart disease who were receiving 2 Gm. of sulfanilamide daily over a period of time as a prophylactic. One of these children, while receiving this dose developed a full-blown case of subacute bacterial endocarditis and, subsequently, died despite the use of other sulfonamide drugs.

DR. WHEELER: I think perhaps we may have gone too far on this. I believe we have not stressed enough the factor of the toxicity of these drugs. When one talks about their prophylactic use, one must remember that their use is attended by considerable risk and that they are not yet so bland as we would like to have them. For example, in the last six weeks we have had 2 patients in this hospital who died as the result of these drugs. One of these patients died from agranulocytosis and the other from thrombocytopenia.

DR. TRAVELL: It would seem, from the point of view of the surgeon, that the risk of withholding sulfonamide drugs might be greater than administering them.

DR. WHEELER: I do not think that Dr. Plummer would want you to carry the impression from here that these drugs are safe to use prophylactically for minor conditions like sinusitis and the common infections of the upper part of the respiratory tract. A good many practicing physicians are using them for those things, but I do not think we would agree with that.

DR. PLUMMER: I wanted to indicate that this field of prophylactic use at the present time is receiving a great deal of consideration. Dr. Bowers indicated the studies in surgery. I know that there is one study being carried out and another one planned on the use of these drugs in colds, with the idea of preventing the serious complications. We must recognize that 95 per cent of cases of pneumonia start with a cold, so that pneumonia is a complication of it. Also, there are cases of mastoiditis and cases of acute sinusitis which start similarly.

VISITOR: At a conference here some time ago it was suggested that sulfonamide drugs may be of some use in acute poliomyelitis. I wonder if anything more definite may be said about this?

DR. PLUMMER: There have been two or three articles published on this subject. The acute stage of poliomyelitis might be affected slightly by the sulfonamide drugs. One of the papers states that the amount of paralysis is less when the sulfonamide drugs are used during the acute stage. Again, there is no strong evidence for this, and I think it is most likely that these drugs affect the course of poliomyelitis very little.

VISITOR: Some patients suffer distressing symptoms from exceedingly small doses of sulfonamides. Are we to interpret that as a toxic reaction, a sensitivity, or an allergic phenomenon due to sulfonamide derivatives?

DR. WHEELER: Dr. Plummer, would you like to answer that?

DR. PLUMMER: That would require some time, but I should like to say that there is a great deal of discussion regarding the mechanism of these reactions. Certainly we know that the hematuria is caused by a mechanical irritation by the sulfonamide crystals. The fevers and rashes, I think, we know little about. They may be allergic.

DR. WHEELER: In the group of 24 cases with toxic reactions which we have studied here in this hospital, there was no correspondence between the duration of treatment, the total amount of drug given, or occurrence of reaction. In other words, a patient is just as likely to have reactions after treatment for three days as after a month.

DR. TRAVELL: Was there any correlation with the blood level?

DR. WHEELER: No.

DR. TRAVELL: One occasionally meets the statement that there is a synergism between sulfonamide derivatives and the barbiturates. Would Dr. Modell comment on that?

DR. MODEL: That statement is based on work with animals in which anesthetic doses of barbiturates were used. With that degree of narcosis there appears to be a toxic, and not therapeutic, synergism. This, however, does not appear to have any bearing on the treatment of humans when small hypnotic doses of barbiturates are used. A survey of a large series in which barbiturates and sulfonamide derivatives were used simultaneously in patients with pneumonia bears this out.

STUDENT: Is there any point in giving sulfapyridine in glucose solution because of the compound formed?

DR. WHEELER: Sulfapyridine with glucose is inert and has no appreciable effect as such. When given orally, it is broken down and absorbed as sulfapyridine and the effect is the same as sulfapyridine.

DR. PLUMMER: It should be pointed out that this applies to all of the sulfonamide drugs. They form an inert glucose compound. For this reason it is unwise to give any of the sulfonamide drugs in glucose solutions.

I think it should be added that promin, which is being investigated in tuberculosis, is also a dextrose combination and probably is just as inert as glucose-sulfapyridine. Given by mouth it probably breaks down into glucose and the active drug, diaminodiphenylsulfone. When given intravenously most of the drug remains in the form of the inert glucose compound.

DR. WHEELER: Dr. Modell, will you sum up for us?

DR. MODEL: Each year we are confronted, and probably will continue to be confronted,

with new additions to the group of sulfonamide derivatives and closely related drugs, and in each new case the problem will arise whether the weighting of its therapeutic value against its toxicity makes the new addition a valuable one. The fundamental pharmacologic and even clinical properties remain similar; the differences between new derivatives are mainly quantitative. The search for a derivative that will be polyvalent, pleasant to take, and nontoxic has not met with striking success. Some of the newer drugs cause less distress, some have a wider antibacterial usefulness, but none is so much less toxic or less dangerous than sulfanilamide itself that the factor of toxicity may be forgotten. Pharmacologic properties, such as differences in the rates of absorption or elimination, type of distribution through the body, degree of acetylation, and the therapeutic specificities, may lead to the choice of one drug over another in a particular case.

Dr. Plummer feels that sulfadiazine may displace all other sulfonamides for most purposes because it presents a combination of clinical effectiveness, low toxicity, and ease of therapy for the patient. In order to exploit its therapeutic potentialities the blood level of the free and acetylated fractions of the drug in the blood stream must be carefully followed in each patient. Without this, one has no notion of whether more or less of the drug is required or whether toxic levels are being approached. And, in addition, if serious mishaps are to be avoided, regular and frequent examinations of the cellular elements of the blood and urinalyses must be made.

A COURSE IN PRACTICAL ORAL PATHOLOGY TO BE GIVEN

A short course in Practical Oral Pathology will be given by Professor Lester R. Cahn at the School of Dental and Oral Surgery of Columbia University in April, 1942. It is the purpose of this course to present the pathology of the oral cavity in such a way that the practitioner will be aided in recognizing and treating the commoner diseases of the mouth.

The following subjects will be discussed: inflammation; diseases of the jaw bones; tumors;

lesions of the soft tissues including the blood dyscrasias and the avitaminoses; the biopsy and methods of performing this important diagnostic operation; indications for clinical laboratory tests; and the interpretation of laboratory reports.

The seminar method of teaching will be used. There will be recourse to case histories as much as possible, and free discussion will be encouraged. —HOUGHTON HOLLIDAY, Associate Dean

QUIZ ENDS WHIZ

The human brain is certainly a wonderful organ. It starts functioning the minute you get up and never stops until you get in quiz section. —Dodo

Maternal Welfare

From time to time under this heading articles will appear on obstetric subjects which are deemed of importance as aids to improvement of maternal welfare in New York State. The members of the committee are Charles A. Gordon, M.D., Chairman; Alexander F. Martin, M.D., James K. Quigley, M.D.; and Ferdinand J. Schoeneck, M.D.

Obstetric Consultant Service

NATIONAL funds have been available for some time to provide obstetric consultation for cases needing such service but unable to pay for it. The Maternal, Infancy and Child Hygiene Division of the New York State Department of Health and the Subcommittee on Maternal Welfare of the Medical Society of the State of New York have been actively interested in establishing such a service in New York State. This subject has received considerable attention and is now at the stage of being actually set up so that the plan can be put in operation.

Two years ago the Subcommittee on Maternal Welfare divided the entire state into twelve regions and appointed a Regional Chairman in each district. This plan had as its object the establishing of methods and means of improving obstetric conditions in general and the facilitating of postgraduate education. The present plan, however, intends to provide actual obstetric consulting service. It is the intent to have such consultants available in all parts of the state so that the local physician caring for an obstetric patient may call in the consultant for any complication that might develop. It is hoped that even in the most remote parts of the state such service will be available within a 50-mile radius of any particular point.

Trained obstetricians are available in most localities of the state at the present time. However, a survey by the Subcommittee on Maternal Welfare does show that there are some areas where this condition does not exist. In these areas, however, obstetricians are almost invariably available from adjacent counties or nearby communities. It is the aim of the plan to have available consultant service in all areas so that the individual physician needing obstetric consultation for any emergency can get such help by contacting the district health officer who will have the list of consultants.

This service will be limited to those patients who are, in the opinion of the attending physician, unable to afford a private consultant. This would include welfare cases, but these patients need not have a recognized relief status. The plan is not intended to interfere with the present custom of consultation in private practice. The object is to provide consultant service for pa-

tients unable to pay for private consultation.

The matter of compensation will be handled by the State Department of Health. Following the providing of consultant service, each consultant will be expected to submit a brief statement including the name and address of patient, the date, and the condition for which consultation was secured to the district health officer in order that arrangements may be completed for his receiving the stipulated fee (\$15 including travel) from the State Health Department. This plan will not change the status of compensation for local physicians handling welfare cases.

The qualifications for obstetric consultants are listed as follows: (a) graduate from an approved school of medicine; (b) one year's internship; (c) not less than four years' training and experience in obstetrics, at least two years of which have been spent in graduate specialized training; and (d) preferably limit work to obstetrics.

These qualifications have been interpreted to include licentiates of the American Board of Obstetrics and Gynecology.

The various county societies are being canvassed to provide the Subcommittee on Maternal Welfare with lists of qualified obstetricians who are willing to cooperate in this service. The lists will then be submitted to the State Department of Health. Appointment to the consulting service will then be made by the State Department of Health and the lists will be supplied to the local district health officers.

It is the studied opinion of the Subcommittee on Maternal Welfare that such a state-wide obstetric consultant service will be of definite value.

In the present emergency it is somewhat difficult to arouse enthusiasm over any matter that does not apply directly to national war effort. The matter of maternal welfare is one that is extremely important, in peace time. A little thought will show that it is equally important during an emergency, perhaps, even more so. The Subcommittee on Maternal Welfare, therefore, requests that this matter be given due consideration and asks the cooperation of all physicians in the state whose services, directly or indirectly, may make this plan a success.

Medical Preparedness

[The following letter and release were received on January 19, 1942.—Editor]

Editor, Journal American Medical Association
Editors, State Medical Journals
Secretaries, State Medical Associations

Inasmuch as this material represents one of the most important responsibilities of the medical profession at the present time, it is the opinion of the Assignment and Procurement Service that it deserves the most prominent place in your Journal it can be given. It is of equal importance to doctors themselves since it clarifies quite largely the demands which will be made upon the medical profession.

Sincerely yours,

FRANK H. LAHEY, M.D., *Chairman*
HARVEY B. STONE, M.D.
JAMES E. PAULLIN, M.D.
HAROLD S. DIEHL, M.D.
C. WILLARD CAMALIER, D.D.S.

SAM F. SEELEY, M.D.
Executive Officer

Recommendations to All Physicians with Reference to the National Emergency

I. Medical Students

A. All students holding letters of acceptance from the Dean for admission to medical colleges and freshmen and sophomores of good academic standing in medical colleges should present letters or have letters presented for them by their deans to their local boards of the Selective Service System. This step is necessary in order to be considered for deferment in Class II-A as a medical student. If local boards classify such students in Class I-A, they should immediately notify their deans and if necessary exercise their rights of appeal to the Board of Appeals. If, after exhausting such rights of appeal, further consideration is necessary, request for further appeal may be made to the State Director and if necessary to the National Director of the Selective Service System. These officers have the power to take appeals to the President.

B. Those junior and senior students who are disqualified physically for commissions are to be recommended for deferment to local boards by their deans. These students should enroll with the Procurement and Assignment Service for other assignment.

C. All junior and senior students in good standing in medical schools, who have not done so, should apply immediately for commission in the Army or the Navy. This commission is in the grade of Second Lieutenant, Medical Administrative Corps of the Army of the United States, or Ensign H.V. (P) of the United States Navy Reserve, the choice as to Army or Navy being entirely voluntary. Applications for commission in the Army should be made to the Corps Area Surgeon of the Corps Area in which the applicant resides and applications for commission in the Navy should be made to the Commandant of the Naval District in which the applicant resides. Medical R.O.T.C. students should continue as before with a view of obtaining commissions as First Lieutenants, Medical Corps, upon graduation. Students who hold

commissions, while the commissions are in force, come under the jurisdiction of the Army and Navy authorities and are not subject to induction under the Selective Service Act. The Army and Navy authorities will defer calling these officers to active duty until they have completed their medical education and at least 12 months of internship.

II. Recent Graduates

Upon successful completion of the medical college course, every individual holding commission as a Second Lieutenant, Medical Administrative Corps, Army of the United States, should make immediate application to the Adjutant General, United States Army, Washington, D. C., for appointment as First Lieutenant, Medical Corps, Army of the United States. Every individual holding commission as Ensign H.V. (P), U. S. Navy Reserve, should make immediate application to the Commandant of his Naval District for commission as Lieutenant (J.G.) Medical Corps Reserve, U. S. Navy. If appointment is desired in the grade of Lieutenant (J.G.) in the regular Medical Corps of the U. S. Navy, application should be made to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

III. Twelve Months' Internes

All internes should apply for a commission as First Lieutenant, Medical Corps, Army of the United States, or as Lieutenant (J.G.), United States Navy or Navy Reserve. Upon completion of 12 months' internship, except in rare instances where the necessity of continuation as a member of the staff or as a resident can be defended by the institution, all who are physically fit may be required to enter military service. Those commissioned may then expect to enter military service in their professional capacity as medical officers; those who failed to apply for commission are liable for military service under the Selective Service Acts.

IV. Hospital Staff Members

Internes with more than 12 months of internship, assistant residents, fellows, residents, junior staff members, and staff members under the age of 45, fall within the provisions of the Selective Service Acts which provide that all men between the ages of 20 and 45 are liable for military service. All such men holding Army commissions are subject to call at any time and only *temporary deferment* is possible, upon approval of the application made by the institution to the Adjutant General of the United States Army certifying that the individual is temporarily indispensable. All such men holding Naval Reserve commissions are subject to call at any time at the discretion of the Secretary of the Navy. Temporary deferments may be granted only upon approval of applications made to the Surgeon General of the Navy.

All men in this category who do not hold commissions should enroll with the Procurement and Assignment Service. The Procurement and Assignment Service under the Executive Order of the President is charged with the proper distribution of medical personnel for military, governmental, industrial, and civil agencies of the entire country. All those so enrolled whose services have not been established as essential in their present capacities will be certified as available to the Army, Navy, governmental, industrial, or civil agencies requiring their services for the duration of the war.

V. All Physicians Under Forty-Five

All male physicians in this category are liable for military service and those who do not hold

commissions are subject to induction under the Selective Service Acts. In order that their service may be utilized in a professional capacity as medical officers, they should be made available for service when needed. Wherever possible, their present positions in civil life should be filled or provisions made for filling their positions, by those who are (a) over 45, (b) physicians under 45 who are physically disqualified for military service, (c) women physicians, and (d) instructors and those engaged in research who do not possess an M.D. degree whose utilization would make available a physician for military service.

Every physician in this age group will be asked to enroll at an early date with the Procurement and Assignment Service. He will be certified for a position commensurate with his professional training and experience as requisitions are placed with the Procurement and Assignment Service by military, governmental, industrial or civil agencies requiring the assistance of those who must be dislocated for the duration of the national emergency.

VI. All Physicians over Forty-Five

All physicians over 45 will be asked to enroll with the Procurement and Assignment Service at an early date. Those who are essential in their present capacities will be retained and those who are available for assignment to military, governmental, industrial or civil agencies may be asked by the Procurement and Assignment Service to serve those Agencies.

The maximal age for original appointment in the Army of the United States is 55. The maximal age for original appointment in the Naval Reserve is 50 years of age.

All inquiries concerning The Procurement and Assignment Service should be sent to The Executive Officer, 5654 Social Security Building, 4th and Independence Avenues, SW, Washington, D. C., and not to individual members of the Directing Board or of committees thereof.

[The article reprinted below is from the December issue of the Nassau Medical News and tells in brief how Nassau County has been organized for wartime emergency. The thorough preliminary work accomplished during the past year and a half effected mobilization of doctors within a few minutes after the air-raid alarm sounded on December 9.—Editor]

The Society Mobilizes

EIGHTEEN months ago the Medical Preparedness Committee of this Society started planning for the possibility of war reaching our borders. The air-raid alarm of December 9 therefore found us with plans well advanced and within a very few minutes the doctors of the county were mobilized and ready for any casualties which might have resulted. At the request of the Nassau County Defense Council, the Society drew up plans which have been accepted and approved by the Nassau County Defense Council which issued General Orders

No. 2 on December 12 under which a large share of the doctors were assigned to definite duty in the event of emergency.

Hospital—the Focal Point

We can safely say to the people of the county that the doctors are ready, but in saying so we feel that the people should also be told what we have done and why we have done it. Every phase of this complicated problem might not be immediately apparent to one who has not been closely associated with it.

The experience with civilian casualties in Spain and in England has demonstrated very clearly that the hospital is the most important link in the chain of civilian medical protection. In fact it has been stated that the less work there is done outside of the hospitals, the lower will be the mortality rate of civilian air raid victims. The Office of Civilian Defense in Washington recognizes this fact, and in their outline of recommended procedure the hospital becomes the focal point for all civilian medical preparations.

Local Defense Councils

Again, the county has been divided into 55 local defense councils. Some of these councils have large areas with scattered population and few or no doctors. Others with concentrated population have plenty of doctors—but also include the bulk of the physicians who will be needed at the hospitals. Finally there is the problem of unifying and coordinating the efforts and the problem of equipment and supplies.

The work of the Medical Preparedness Committee was therefore directed first of all against two fronts: First, to make certain that all the hospitals would have sufficient medical personnel to handle the maximum number of patients their physical facilities would permit; second, to make certain that every section of the county would have adequate medical service immediately available regardless of the number of physicians actually residing within the area.

Doctors Assigned to Hospitals

Several months ago the Committee on Hospital and Clinic Relations began preparing a list of physicians needed at each of the several hospitals in the event of emergency and making definite assignments to a particular hospital in cases where the physician had staff appointments at more than one institution. These assignments were made on the basis of lists submitted by the hospitals themselves and duplicate requests were straightened out by consultation with members of the hospital staff officially designated to represent the institution on our Hospital Committee.

Medical Districts

This important work had been completed before the attack on Pearl Harbor plunged the United States into war. The next step was to complete the division of the county into medical districts, 21 in number, with a medical director in charge of each, and to organize field casualty teams which could be sent at once into any affected area for work in the field. Only when all these groups were selected was it possible to consider the designation of men for duty at the first-aid stations of the local defense councils.

Many of the councils had proceeded to select physicians as requested by the County Council. In these cases every effort was made to approve their selections. Unfortunately, some of the councils had nominated men of vital importance in other fields of medical activity. In most cases these councils recognized the need for coordinated effort and immediately made another selection. It is hoped that within a few days all of the local councils will be organized and medical personnel assigned.

How the Plan Works

Briefly the procedure in the event of casualties is as follows: The local defense councils are being asked to equip and maintain an adequate number of first-aid posts under the direction of a physician. These local posts will render first aid only but will also be responsible for all movement of patients from the field into the first-aid station. If the physician in charge has more casualties than he can handle with his own resources, he will appeal for help to the medical director of his own district. If the situation is too serious for the medical director and his facilities, he will notify the Nassau County Control Center and help will be sent him.

Local areas should assemble first-aid supplies and equipment for their own first-aid posts; other supplies will be furnished them in emergencies by their district medical director with the help of the central authority. Each district director will utilize to the limit all local facilities including hospitals other than those designated as base hospitals, private sanatoriums, nursing homes, local nurses and first-aid workers and other volunteers, but no patient is to be evacuated out of the district except upon orders issued by the operating head of the health division of the county council.

Every Physician to Help

Eventually, all the doctors in Nassau County will be given an opportunity to participate in this voluntary patriotic effort. The Medical Directors of the 21 districts are now helping local defense councils select doctors for first-aid posts; they are selecting first-aid teams to be sent from place to place within their districts as the need may arise or to be "loaned" to other districts which might suffer serious damage; and finally, they are selecting physicians who will be asked to stand by at their own offices for emergency work or to be sent as reinforcements as they might be needed.

The medical directors of the districts will be responsible for all medical work within their territory and will report directly to the Operating Head of the Health Division of the Nassau County Defense Council, Dr. Earle G. Brown. Through Dr. Brown they will be able to secure help from the splendid preparations made by the American Red Cross, the local hospitals and the local branch of the New York State Nurses Association. Ambulances, first-aid equipment and supplies, nurses and lay workers will be available to be rushed into any corner of the county where the need arises, and through him also they will secure help for patients requiring hospital care. In order to promote efficiency, Dr. Brown will have constantly up to date a record of the available beds in each institution and will thus be able to decide where casualties shall be sent.

Organization of Nurses and Volunteers

The Nurses Association has completed an inventory of the nurses of the county, both active and retired, about 1,200 in number. From this list nurses will be selected for every phase of the work and their organization is completed along lines strictly parallel to the medical organization. The Red Cross is building up a group of emergency ambulances, mostly station wagons and

their volunteer drivers, and stores of first-aid equipment and supplies are being augmented daily; their first-aid courses are being given to large numbers. The druggists of the county are preparing emergency medical kits to be available in every local area. The Dental Society is organizing its members.

Cooperation with Defense Council

Every group and organization in the county is

at work under full steam and offering its services to the central authority of the Nassau County Defense Council.

The Medical Society, having finished its preliminary work, has now subordinated itself completely to orders from the Nassau County Defense Council and is working under its direction.

From now on, this is War and we recognize authority.

Medical and Surgical Relief Committee of America *Needs Your Help*

"We are now concentrating our efforts on aid to America in close cooperation with the United States Office of Civilian Defense. We have already provided a number of emergency medical field sets to defense officials in target areas throughout the country and plans are now under way to raise funds for the purchase of a sufficient number to meet nation-wide civilian needs."

MRS. ROGERS BALCOM,
Executive Chairman

An Emergency Medical Field Set consists of two portable cases equipped with instruments and supplies that can be readily carried by physicians, nurses, and nurses' aides from hospitals and casualty stations where they are consigned directly to the scene of disaster in emergencies.

Cost: \$110.00 including insurance and handling.

A name plate with the following inscription will be affixed to each set donated:

EMERGENCY MEDICAL FIELD SET

A PSYCHIATRIST LOOKS AT WAR

War is a disease of nations, a national psychosis that needs psychiatric care if the frightful scourge is to be eliminated.

Prevention of maladjustment in men and in nations must be achieved.

The cure is an international mental hygiene movement which brings the understanding of men to such a pitch that no warped and distorted person driven by unsatisfiable urges can victimize the normal and, through cheap tricks of mass

deception, so play on the weakness of the human personality that individually or in groups it can be led out to slaughter. A good psychiatrist in Vienna might have prevented Hitler, but it will take the organization of all educated people to so enlighten the world that war will not only be outlawed but its very roots—inferiority, sadism, and the love of killing—shall be so adjusted that they will cease to menace the people of the earth.—
David C. Wilson, M.D., in the Southern Med. J.

(Number three in a series of six)

Common problems in the management of peptic ulcer

"How can the ulcer patient be returned
to his job and kept there?"

Clinical evidence shows that a regimen of
Amphojel*—diet and rest results in more rapid
healing of peptic ulcer. Amphojel aids the ulcer
patient to lead a more normal life.

Four striking features of Amphojel, Wyeth's
Alumina Gel, are recognized by clinicians:

Amphojel provides prompt relief from pain. It
permits rapid healing of the ulcer. It cannot be
absorbed and eliminates the hazard of alkalosis.
It reduces excess acidity without completely
neutralizing the gastric contents.

Amphojel is a valuable adjunct in the treatment
of melena and hematemesis when administered by
continuous drip

AMPHOJEL

*Wyeth's
Alumina Gel*

Amphojel, Wyeth's Alumina Gel
Fluid Antacid . . . Adsorbent

One or two teaspoonfuls either undiluted or
with a little water, to be taken five or six
times daily, between meals and on retiring.
Supplied in 12-ounce bottles

*For the Convenience of Ambulatory
Patients*

Wyeth's Hydrated Alumina Tablets
Antacid

One-half or one tablet in half a glass of
water. Repeat five or six times daily, between
meals and on retiring

Supplied in boxes of 60 tablets

Women's Medical Society of New York State Holds Midyear Meeting

THE Women's Medical Society held their mid-year meeting on January 24 and 25. Many of the 1,450 women physicians throughout the state attended the two-day session which opened on the morning of the twenty-fourth at the New York Infirmary for Women and Children, 325 East 15th Street, New York City.

After the Councillors' meeting and the regular business session, the following scientific program was heard: "Arterio-Sclerotic Peripheral Vascular Disease," Dr. Theresa McGovern, Post-Graduate Hospital, discussion by Dr. Alice Bernheim, of New York Hospital; "The Use of the Blood Sugar Curve as a Diagnostic Test in Patients Presenting Endocrinological Symp-

toms," Dr. Julia Lichtenstein, First Medical Division of New York Hospital, discussion by Dr. Gertrude Felshin.

Luncheon was at Luchow's—one of New York City's oldest and most famous restaurants. Dinner at Theresa Worthington Grant's was held in conjunction with the Women's Medical Society of New York City.

On Sunday afternoon the members attended the Philharmonic Symphony Concert.

Dr. Marguerite P. McCarthy is president and Dr. Isabelle F. Borden is secretary of the society.

Dr. Frances H. Bogatko was chairman of arrangements.

County News

Cayuga County

Dr. L. D. Burlington, of Aurora, was elected president of the county society at the annual dinner meeting held on December 18.

Other officers elected are: vice-president, Dr. D. D. Althouse, Auburn; secretary, Dr. Bernard L. Cullen, Auburn; treasurer, Dr. Leonard H. Rothschild, Auburn.

Dr. Harry S. Bull, Auburn, was elected delegate to the meeting of the New York State Society and Dr. H. I. Davenport, Auburn, alternate.

Dr. Wilfred Sefton, retiring president, presided and introduced Dean M. Lyle Spencer of the College of Journalism, Syracuse University.

"We Americans need to be reminded now and then that racially and culturally we are a nation of mongrels," Dean Spencer told the society in a talk entitled "America As I Know It."

"We are not a homogeneous people in the sense that the population of England, Italy, or Japan is. We are not British, Polish, German, or French. We are not predominantly Anglo-Saxon any more," Dean Spencer said. "Consequently we are not now, and never have been, a national unit. We have never been wholly integrated. . . ."

About seventy-five were present, including wives of the medical men.

Cortland County

At the annual meeting on December 19 the following officers were elected: president, Dr. Charles Osborne Mills; vice-president, Dr. Wm. Anthony Shay; secretary, Dr. Wm. Arthur Wall; and treasurer, Dr. Bert Ross Parsons—all of Cortland.

The president has appointed committees as follows: Legislation, Drs. Wm. Arthur Wall, James Walsh, and Stewart A. VerNooy, of Cortland; Compensation-Arbitration, Drs. Reuben Paul Higgins, Charles J. Kelley, and John E. Wattenberg, of Cortland; Economics, Drs. James Walsh, Wm. Anthony Shay, Anthony Vincent Runfola, of Cortland; Cancer Control, Drs. Robert H. Brink and Warren James Pashley, of Cortland, and Roger James Reid, of Truxton; Military Preparedness, Drs. Charles

J. Kelley, Wm. Anthony Shay, and Daniel Robert Reilly, of Cortland; Medical Care to the Indigent, Drs. Bert Ross Parsons, of Cortland, Wm. F. Newcomb, of Homer, and Louis John Iacovino, of Cortland; Public Health, Drs. Claude E. Chapin and Hugh Frail, of Cortland, Donald Briggs Glezen, of Cincinnati, and Wm. Eugene Mosher, Jr., and Roxie A. Weber, of Cortland.—*W. A. Wall, Secretary.*

Delaware County

At the annual meeting on December 16 the following officers were elected: president, Dr. Floyd Robert Bates, of Walton; vice-president, Dr. Fisk Brooks, of Delhi; secretary-treasurer, Dr. Elliott Danforth, of Sidney.—*O. Q. Flinl, Secretary.*

Dutchess County

At the regular meeting of the county society on January 14, held at Ryon Hall, Hudson River State Hospital, Poughkeepsie, Dr. Samuel J. Kopetzky, president of the State Society, spoke on "Physicians in National Defense."

Erie County

During January the following speakers addressed the Buffalo Academy of Medicine: Dr. Louis C. Kress, of Albany, on "Every Day Cancer," January 7; Dr. Francis G. Blake, professor of medicine, Yale University, on "Treatment of Pneumonia," January 14; Dr. J. Bay Jacobs, of Washington, D. C., on "Management of Labor and Outcome in 800 Women with Borderline Pelves," on January 21.

Franklin County

On February 17 the third session of the course on sulfonamide therapy will be held at the Elks Club in Malone. Dinner at six-thirty will be followed by the program. The subject is "Treatment of Pneumonia and Meningitis." A panel discussion (internist, pediatrician, surgeon) will be held. Questions will be presented in writing either before or during the panel, which will be conducted by Dr. Robert H. E. Elliott, Jr.,

[Continued on page 274]

Presenting the "KOROMEX SET COMPLETE"

Koromex Set Complete* provides the long expressed need for a compact unit containing the three important items used for approved contraceptive technique. This attractive and strongly built case is identified by an easily removed label, convenient for dispensing or prescription purposes. To order or prescribe, merely write, "Koromex Set Complete. Diaphragm Size_____".

KOROMEX DIAPHRAGM—The outstanding, most durable diaphragm made. Backed by the most extensive record in clinical use ever attained by any diaphragm. In special sanitary pouch.

KOROMEX TRIP RELEASE INTRODUCER—The latest development in introducers. Swivel tip facilitates usage.

KOROMEX JELLY and H-R EMULSION CREAM—Both preparations have equally high spermicidal value, but differ greatly in the amount of lubrication afforded. A tube of each is here offered so the patient may determine for herself which type of preparation better meets her aesthetic requirements and her personal preferences.

* Price of the Koromex Set Complete is only that of the Koromex Diaphragm and the Koromex Trip Release Introducer.

[Continued from page 272]

instructor in surgery, College of Physicians and Surgeons.

Preceding the panel discussion, Dr. J. Whittington Gorham, professor of medicine, Albany Medical College, will talk on "Treatment of Pneumonia" and Dr. Harry Bakwin, associate professor of pediatrics, New York University Medical College, will speak on "Treatment of Meningitis."

The course, arranged by the Council Committee on Public Health and Education of the State Society and the New York State Department of Health, held its first session on December 16 when Dr. K. Jefferson Thomson spoke on "Behavior of Sulfonamides in the Body and Principles for Their Use" and Dr. Eldridge H. Campbell spoke on "Local and Internal Use of Sulfonamides in Surgery."

The second session in January had as speakers Dr. William A. Brumfield, Jr., and Dr. R. Gordon Douglas. Their subjects were: "Treatment of Genitourinary Infections in the Male" and "Sulfonamides in Obstetrics and Gynecology."

Madison County

The following course on sulfonamide therapy, arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York and the New York State Department of Health, was given during January.

First session: "Behavior of Sulfonamides in the Body and Principles for Their Use," Dr. Alexander D. Langmuir; "Local and Internal Use of Sulfonamides in Surgery," Dr. Eldridge H. Campbell.

Second session: "Treatment of Genitourinary Infections in the Male," Dr. Allister M. McLellan; "Sulfonamides in Obstetrics and Gynecology," Dr. Edward C. Hughes.

Third session: "Treatment of Pneumonia," Dr. George M. Mackenzie; "Treatment of Meningitis," Dr. John A. Lichty, Jr.; Panel Discussion (internist, pediatrician, and surgeon), Dr. Frank Glenn.

Monroe County

Despite the war the county society has not shelved consideration of a nonprofit, medical expense indemnity insurance plan according to Dr. Edward T. Wentworth, chairman of a special committee that for more than a year has been weighing various aspects of the plan.

In the society's *Bulletin*, Dr. Wentworth said: "We have not given up the thought of the possibility of this insurance, but from our point of view this is a poor time to introduce such a plan. There is a good deal of skepticism concerning the salability of such policies. The people who need them most cannot afford to pay the premium."

"We have yet to hear of any community which has successfully run such a plan, but when we do we shall attempt to adapt it to the needs of this community and put it into effect here. We suggest that the committee be continued to serve as a reception center for any ideas that may be advanced on the subject."

Nassau County

For the series of lectures on war surgery and the county emergency setup see pages 251 and 268 of this issue.

A letter from the county society office concludes with this heartening paragraph:

"I think you will also be interested to know that as a result of our early preliminary work, going back over a period of one and a half years, the air-raid alarm of December 9 found our plans so well advanced that within fifteen minutes every hospital in the county had on hand ready for duty a larger staff of physicians than would have been needed had casualties resulted. These men were, of course, ready to be sent immediately to any affected area. Since that time our plans have been further refined so that it will not be necessary to tie up such a large number of doctors at the hospitals, but arrangements have been completed whereby the physicians will be available without delay in any section of the county where help might be needed including the manning of first-aid stations, field casualty units, and base hospitals."

Niagara County

The county society held its annual election of officers in the Niagara Falls Country Club, Lewiston Heights, on December 9. The following officers were elected: president, Dr. Forrest W. Barry, Lockport; vice-president, Dr. Harry C. Dumville, Niagara Falls; secretary, Dr. Charles M. Dake, Jr., Niagara Falls; treasurer, Dr. Dudley B. Fitz-Gerald; censors, Dr. R. R. B. Fitz Gerald, Lockport, Dr. Roy H. Wixson, Niagara Falls, and Dr. Theodore E. Mueller, North Tonawanda.

The following committee chairmen were also appointed: Legislation, Dr. E. M. G. Rieger, Niagara Falls; Public Health and Medical Education, Dr. John C. Kinzly, North Tonawanda; Economics and Public Relations, Dr. William A. Peart, Sanborn.

Delegates to the State Convention are: Dr. William A. Peart, Sanborn, and Dr. Guy S. Philbrick, Niagara Falls; Alternates, Dr. Raymond S. Barry, Niagara Falls, and Dr. Harley U. Cramer, Lockport.—*Charles M. Dake, Jr., M.D., Secretary.*

Onondaga County

During January the society had a post-graduate course on sulfonamide therapy which was arranged by the Council Committee on Public Health and Education of the State Society and the New York State Department of Health.

On January 15 the speaker was Dr. George M. Mackenzie whose subject was "The Behavior of Sulfonamides in the Body and Principles for Their Use." Dr. Eldridge H. Campbell talked on "Local and Internal Use of Sulfonamides in Surgery."

At the second session Dr. R. R. Wolcott and Dr. Charles H. Peckham had as their subjects "Treatment of Genitourinary Infections in the Male" and "Sulfonamides in Obstetrics and Gynecology," respectively.

Dr. Harry Bakwin and Dr. Norman Plummer were the speakers for the session on January 29.

ARGYROL

Suffusion

Tampon Insertion

Decongestion

Tampon Removal

Improved Acuity

DECONGESTION WITHOUT VASOCONSTRICTION

Safe and Effective Mucous Membrane Therapy

● The ocular suffusion and decongestion incident to the Dowling tampon treatment indicate that ARGYROL'S action is physiological as well as chemical—that it marshals to its aid many of the natural defensive processes in combating infection.

The insertion of an ARGYROL tampon into the nose, often produces an intense injection and suffusion of the conjunctiva followed by decongestion. Indeed, ocular congestion present *before* the tampon insertion is frequently improved by this method, and visual acuity may be rendered more acute.

This then is evidence of ARGYROL'S ability to achieve decongestion not only of the nasal blood vessels, but of the entire head, *without resort to powerful vasoconstriction*. Add to this, ARGYROL'S freedom from irritating properties in any concentration from 1% to 50%, the fact it is non-injurious to the cilia, its ultra fine colloidal dispersion and highly active Brownian movement, its controlled pH and pAg, and its remarkable soothing properties, and you have a few of the reasons why ARGYROL is the overwhelming choice of specialists in treatment of mucous membrane infections.

Ontario County

The regular first quarterly meeting of the county society was held at the Canandaigua Hotel on January 13. A dinner followed the business meeting and later Dr. William G. Farlow, of Rochester, spoke on "Surgical Chest Problems Today."

Orange County

At the annual meeting held on December 9 the following officers were elected for 1942: president, Dr. George R. Dempsey, of Cornwall; vice-president, Dr. Earl R. Van Amburg, of Pine Bush; secretary-treasurer, Dr. Earl Charles Waterbury, of Newburgh.—*E. C. Waterbury, M.D., Secretary.*

On January 7 the Medical Board of the Cornwall Hospital began a series of postgraduate lectures. The lectures are being given each Wednesday evening for twelve weeks, ending April 1. The speakers are members of the teaching staff of the College of Physicians and Surgeons of Columbia University and the series is on the subject of "Diagnosis of Disease and Modern Therapy."

Orleans County

The annual meeting and election of officers were held at the Town Club in Albion on December 18. The officers re-elected were: president, Dr. Julius J. Layer, Lyndonville; vice-president, Dr. James Arthur Elson, Albion; secretary, Dr. Ellen Mary Nicholson, Albion; treasurer, Dr. Edward T. Eggert, Knowlesville; delegate, Dr. John Dugan, Albion; alternate, Dr. Howard Robert Lawrence, Medina; censors, Dr. Ralph Earle Brodie and Dr. John Dugan, Albion, and Dr. Charles Eugene Padelford, Holley.

A letter was read by the chairman of the special advisory committee from the newly elected commissioner of welfare expressing his sincere desire to cooperate with the physicians of the county in all ways and to settle, satisfactorily to both parties concerned, any differences of point of view or opinion which might arise.

This special advisory committee of the county society was empowered to present the names of three physicians to the commissioner of welfare, one of whom the latter would appoint as medical consultant to his department.

Dr. Nelson Russell, of Buffalo, later addressed the society on "Rheumatic Heart Disease."

Following the meeting, a dinner was held at the Town Club.—*Ellen M. Nicholson, Secretary.*

Oswego County

Dr. John F. Burden has been elected president of the county society. Dr. Emerson J. Dillon, Phoenix, was named vice-president and Dr. Francis Lee, Oswego, secretary and treasurer.

Otsego County

The following officers were elected on December 10 at the annual meeting: president, Frederick Baker Devitt, of Oneonta; vice-president, John Wayne Latcher, of Oneonta; secretary, Marjorie F. Murray, of Cooperstown; treasurer, Paul von Haeseler, of Gilbertsville; censor, Earle C. Winsor, of Schenectady; delegate to the

State Convention, James Greenough, of Oneonta; alternate delegate, Alexander F. Carson, of Oneonta.—*Marjorie F. Murray, M.D., Secretary.*

Rensselaer County

At the annual meeting on December 9 the following officers were elected: president, Dr. John Oswald Sibbald, Troy; vice-president, Dr. Alson Joye Hull, Troy; secretary, Dr. Elizabeth Palmer, Troy; treasurer, Dr. Francis James Fagan, Troy; censors, Dr. William Trotter, Troy, and Dr. Charles Henry Sproat, Valley Falls; delegates, Dr. Stephen Horace Curtis and Dr. John D. Carroll, Troy; alternates, Dr. Clement Joseph Handron and Dr. George Francis Reed, Troy.—*Elizabeth Palmer, Secretary.*

Dr. Eugene F. Connally, a major in the first World War who saw services on the Mexican border and in France, has been appointed to take charge of the First-Aid Detachments of Rensselaer County Chapter, Red Cross.

Saratoga County

At the meeting on January 15, held at the Saratoga Hospital, the topic was "Defense." Dr. John T. Geiger, assistant medical director of the Metropolitan Life Insurance Company, was the speaker.

Schenectady County

At the meeting on January 6, held in the Ellis Hospital Nurses Home Auditorium in Schenectady, the speaker was Dr. Merrill C. Sosman, professor of x-ray at Harvard Medical School and a member of the Department of Roentgenology of the Peter Bent Brigham Hospital, Boston. His subject was "A Trip Through the Alimentary Canal with the Roentgenologist."

St. Lawrence County

The last of three sessions on sulfonamide therapy, arranged by the Council Committee on Public Health and Education of the State Society and the New York State Department of Health, will be given in Ogdensburg on February 5.

Luncheon at the Hepburn Hospital will be followed by this program: (1) "Treatment of Pneumonia," Dr. George V. Taplin, instructor in medicine, University of Rochester School of Medicine and Dentistry; (2) "Treatment of Meningitis," Dr. A. Wilmot Jacobsen, associate professor and chairman of the Department of Pediatrics, Buffalo University, School of Medicine; (3) Panel Discussion (internist, pediatrician, and surgeon), Dr. G. Stuart Welch, instructor in anatomy and surgery, Albany Medical College.

At the first session of the course on January 8, Dr. K. Jefferson Thomson spoke on "The Behavior of Sulfonamides in the Body and Principles for Their Use." Dr. Leon E. Sutton had as his subject "Local and Internal Use of Sulfonamides in Surgery."

On January 22 the second session was held. Dr. Thomas F. Laurie lectured on "Treatment of Genitourinary Infections in the Male" and Dr. James Lamont Crossley talked on "Sulfonamides in Obstetrics and Gynecology."

Washington County

The quarterly meeting of the society was held

Smokers Can't Help Inhaling—but *they can help their throats!*

ALL those who smoke inhale — at least sometimes. And *when* they inhale, the danger of irritation increases. Therefore, the importance of this Philip Morris advantage:

The irritant quality in the smoke of four other leading brands was shown in recognized laboratory tests* to average more than three times that of the strikingly contrasted Philip Morris.

Further—the irritant effect of such cigarettes was observed to last more than 5 times as long!

A change to Philip Morris cigarettes will minimize irritation due to smoking.

on January 13 at the Health Center in Whitehall. Dr. K. Jefferson Thomson, associate physician of the Metropolitan Life Insurance Company Sanitorium, Mount McGregor, addressed the meeting on "The Diagnosis and Treatment of Heart Disease in Pregnant Women."

Westchester County

At the regular meeting held January 20 at the New York Hospital, Westchester Division, White Plains, Dr. Max A. Goldzieher, of Brooklyn, spoke on "Diagnosis and Treatment of Pituitary Disease." Dr. Goldzieher was formerly professor of pathology at the Royal Hungarian University in Budapest. At present he is endocrinologist at the Gouverneur and Brooklyn Woman's hospitals.

The regular meeting of the county society in February will be held on Tuesday evening, February 17. This will be a combined meeting with the Westchester Society of Gastroenterol-

ogy. The guest speaker will be Dr. I. S. Ravdin of Philadelphia, whose topic will be "Nutritional Aspects of Surgical Patients." Ravdin is the Harrison Professor of Surgery at the School of Medicine, University of Pennsylvania, and Director of the Harrison Department of Surgical Research at the same school. He also serves as attending surgeon at the hospital of the University of Pennsylvania. Ravdin's paper was presented recently at a meeting of the College of Surgeons at Boston.

Yates County

Two Dundee pastors, Rev. Harvey R. K. and Rev. Floyd Guiles, have been appointed to the county society, through their representatives Dr. J. P. MacDowell, to set up two community first-aid centers; one at the Methodist Parsonage and the other at the Dundee Baptist Church. These centers will minister to the needs of air-raid victims or refugees from the surrounding community.

Has the number of annual births in the United States passed its peak? Probably. It is estimated that in 1921 there were more than 2,600,000 births in the United States. This was the year in which the postwar boom in the birth rate occurred. After that there was an almost continuous decline to the year 1933, when the number of births was 2,081,232, the lowest figure since the peak year, 1921. After that, the number moved somewhat irregularly up and down with, on the whole, an upward tendency, leading to the 1940 figure of 2,353,988, the highest since 1928. It remains to be seen whether the upward movement will continue to a new all-time high. This would require an increase of about one quarter of a million over last year's figure to match the number of births estimated for 1921.

—Statistical Bulletin, Metropolitan Life Insurance Company

Has the annual number of deaths in the United States passed its peak? We have every reason to hope that for many years to come the excessively high figure for 1918 will not be reached again. In that influenza year the total number of deaths was nearly 1,875,000. In recent years the figure has been of the order of 1,400,000, year 1940 being slightly in excess of 1939 and 1938. The lowest total of annual deaths since 1918 was experienced in 1921, namely 1,250,000—incidentally, in the same year that saw our all-time highest total of annual births. The growth of our population, with an increasing proportion of older persons, will in all probability eventually cause a rise in the total annual deaths beyond the figure for 1918, in spite of our generally improved health conditions.

—Statistical Bulletin, Metropolitan Life Insurance Company

GONADOPHYSIN

(SEARLE)

Improved Anterior Pituitary Gonadotropic Substance (Fresh Gland Extract)

Stable—Potent

Gonadophysin Searle is supplied in dry powder form—as such it remains stable and retains its *full potency*.

Uses

Assuming that a gonadotropic hormone deficiency can be established as the causative factor, Gonadophysin Searle is indicated in—

1. Deficient development of the reproductive system, examples of which are cryptorchidism in the male and infantilism in the female.
2. Menstrual dysfunctions of ovarian origin.
3. Functional or premature menopause, in which functionable ovarian tissue exists.

How Supplied

Packages of three serum-type ampuls, each ampul containing 500 Rat Units of powdered hormone and accompanied by three 5 cc. ampuls of Sterile Solution for dissolving Gonadophysin. Administration is by intramuscular injection.

Write for literature giving full information on administration and dosage.

Hospital News

Psychotherapy in the Hospital

MARBLE columns, polished floors, and shiny furniture may make little or no impression on the patient entering a hospital, but he does remember the kind and sympathetic person whom he first sees. That initial impressions are of incalculable aid or detriment is not debatable, for the feeling incurred in a patient within the first hour of his hospital stay often creates his state of mind for many days to come. And no physician today belittles the importance of a patient's mental attitude.

On the subject of psychotherapy in the hospital Dr. Joseph C. Doane, writing in *Modern Hospital*, has this to say: "Most hospital workers do not fully appreciate the profound effect upon the physical welfare of the sick man or woman made by the impressions that they receive through their special senses. . . . every sight, sound, smell, and spoken word to which the hospital patient is exposed causes a reaction in his nervous system as definite as that of the sensitive plant to the touch of the hand. Every contact with each employee produces a physiochemical emotional reaction expressed in terms of confidence, distrust, respect, fear, or desire to cooperate or combat.

"The greatest possibilities lie in educating all members of the institution's personnel to a proper understanding of the psychology of the patient and his relatives. He who understands the workings of the mind of the sick man has gone a long way toward becoming an efficient hospital servant. . . .

"There are only a few drugs that are wholly specific for any disease, but every patient responds in some degree to good psychotherapy. . . . Just as no doctor can be classed as being highly skilled who does not practice psychotherapy effectively in his day's work, so no hospital can render its best service unless it insists on protecting the nervous systems of its patients."

The author says that discussing the prognosis and progress of disease or describing operative or postmortem findings of other patients in the presence of a sick man is little less than mental cruelty. He lists other barbarous practices such as carrying on painful dressings within the hearing of patients; allowing weeping relatives of a dying patient to be in the plain view and hearing of those who are ill; being inconsiderate of the patient who has had a spinal anesthesia by making unnecessary noise in the operating room.

Dr. Doane concludes that the only remedy is to choose hospital workers for their culture and fineness of psychic and ethical fiber . . . and to weed out the crude and the thoughtless.

General Hospitals Again Urged to Establish Emergency Field Units

THE war in which we are engaged has, more than any war in the history of the world, brought injury and death to the civilian population. In order that the people of the United

States may be protected as far as possible against dangers of enemy action, the Office of Civilian Defense again urges all general hospitals to establish emergency medical field units in accordance with plans outlined in Medical Division *Bulletins 1 and 2*. These bulletins are available for distribution through state defense councils and regional offices of civilian defense.

"Equipment for the field units should be assembled immediately by hospitals from their own reserves, and their field units should be drilled weekly. Where necessary, reserve field units also should be organized with medical, nursing, and trained volunteer personnel derived from the community to supplement regular field units."

GEORGE BAEHR, M.D.,
Chief Medical Officer,
Office of Civilian Defense

Newsy Notes

The entire staff of New Rochelle Hospital, including approximately 500 doctors, nurses, office workers, and all hired help, will be photographed, fingerprinted, and sworn to oaths of allegiance as part of New Rochelle's defense effort.

The step is taken, Superintendent Austin J. Shoneke said, to prevent any possible employment of "fifth columnists" at the hospital and to aid in organizing the hospital into a complete defense unit.

. . . .

Dr. Arthur E. Soper, of Brentwood, has been named superintendent of the Kings Park State Hospital. The appointment became effective January 15, according to an announcement by the New York State Department of Mental Hygiene. Dr. Soper has been first assistant on the staff of the Pilgrim State Hospital since April, 1932.

. . . .

Thomas S. McLane, president of the board of trustees of Roosevelt Hospital, has made public a letter from President Franklin D. Roosevelt congratulating the hospital on the completion of its \$1,000,000 building at 428 West Fifty-ninth Street. The President's letter follows:

"I am glad to know that the Roosevelt Hospital will increase its facilities by opening a new building on January 8. As I cannot be present in person, I am glad to offer a word of congratulation and greeting to all those friends and supporters whose labors are thus brought to a happy completion.

"The Roosevelt Hospital has rendered splendid service to the community since its establishment, and with enlarged quarters I trust it will be able to extend its ministrations to an ever increasing clientele.

SELECTIVE CHEMO THERAPY

For antibacterial chemotherapy there are available a number of related compounds. All have proved highly useful though they differ somewhat in their selective action against the various pathogenic organisms.

Neoprontosil is especially effective against hemolytic streptococci and is of particular value in many infections which are encountered commonly in everyday practice.

Because of its bactericidal action against the invaders of the urinary tract Neoprontosil is efficacious in infections caused by colon, aerogenes and dysentery bacilli and hemolytic streptococci.

Neoprontosil is also employed in some conditions requiring prolonged treatment, particularly ulcerative colitis, because of its relatively lower toxicity.

ORAL AND PARENTERAL MEDICATION

For oral use, Neoprontosil is supplied in tablets of 5 grains and capsules of 3 grains, and for parenteral administration in ampules and in bottles of 2.5 per cent solution and 5 per cent solution.

"My best wishes for the continued success of this noble work.

"Very sincerely yours,
FRANKLIN D. ROOSEVELT"

Dr. Joseph B. Boland, of Troy, has been appointed director of a newly established Tumor Clinic at Mercy Hospital, Buffalo. Dr. Boland assumed his new duties January 1.

For the past six months Dr. Boland has been directing the Pathology Laboratory at Mercy Hospital and has been doing research work in association with the New York State Cancer Institute at Buffalo.

Dr. David Edwards, of East Hampton, was elected president of the Medical Board at Southampton Hospital to succeed the late Dr. Joseph S. Wheelwright at a meeting of that board held recently at Southampton.

The staff of the Veterans' Hospital [Canandaigua] is trained and organized to render aid to the city at large in the event of a gas attack, Dr. Hans Hansen, manager, recently revealed at a meeting where he discussed various phases of chemical warfare.

Doctors, nurses, and attendants, trained in their respective specialties, are in readiness should Canandaigua fall victim to enemy gas bombing, he said, as he pointed out that citizens at large should know something of gas to eliminate mystery and worry and should know what to do in that emergency. Dr. Hansen had considerable experience during the World War in chemical warfare, and his review is timely and educational.

The Mt. Morris Tuberculosis Hospital School, commonly known as Murray Hill School, is the only hospital in the state which provides patients an opportunity to get a complete high school education, leading to graduation within the institution. Last June it graduated 11 students and looks forward to a commencement group of 23 for June, 1942.

The school was begun in October, 1939, at the direction of Dr. N. Stanley Lincoln, superintendent of the hospital that serves Livingston, Steuben, Wyoming, Ontario, Allegany, Genesee, and Orleans counties in western New York. The school program is under the direction of James P. Morris, Hornell. He has had the aid of teachers, who are patients, together with excellent cooperation of thirty-five high schools and the State Department of Education at Albany.

Ten physicians of the junior and senior staffs of St. Joseph's Hospital in Elmira have adopted a schedule under which they take turns sleeping in at the hospital to relieve the institution's lone intern and provide "safe coverage."

"Information Please" is the name of a booklet for patients of United Hospital in Port Chester. It tells briefly the story of the workings of the hospital, together with rules and rates, explaining the reason why a public hospital can seldom meet its expenses out of the fees paid by the patients. It is a well-planned booklet and should help greatly in gaining the cooperation of the patient.

According to the New York *Herald Tribune*, January 15, Dr. Willard C. Rappleye, Commissioner of Hospitals in New York, has disclosed that city-supported hospitals expect 150 of their 858 interns to be called between now and July.

The Rochester Hospital Council has announced an increase of approximately 10 per cent in private and semiprivate room rates for the hospitals in that locality.

At the same time, Wilbur G. Woodams, the council's managing director, said the Rochester Hospital Service Corporation and other insurance groups will be asked to grant corresponding increases in contributions under their contracts.

The Clinical Society of the Beth-El Hospital, Brooklyn, announces the first lecture of the Maimonides Series, "Clinical Significance of the Adrenal Glands," by Dr. Julius M. Rogoff, professor of endocrinology, University of Pittsburgh School of Medicine, on February 26 at 9:00 p.m.

"While New York State has only 10 per cent of the entire population of the United States, it has 15.4 per cent or 46,332 out of a total of 300,000 actively practicing registered nurses in the country," according to the monthly report of the Department of Health on defense activities.

"About 16,000 registered nurse licenses had been issued in the state prior to 1918. A total of 97,000 such licenses have been issued to date. Of the students graduating each year from recognized schools of nursing, 10.4 per cent are from New York State.

"On Armistice Day in 1918 there were 25,999 nurses in active military service. From these figures it would seem evident that New York has a large reserve of nursing power. Some of the factors relating to the 'shortage of nurses' are concerned with the problems of distribution and willingness of nurses to accept positions in the places where there is need." — *Defense Digest*

The American Nurses' Association reported last month that nursing schools throughout the United States have admitted 42,000 new students in the last five months. The goal of 50,000 new student nurses set last summer by Dr. Thomas Parran will probably be met by spring.

Woman's Auxiliary

To the Medical Society of the State of New York

THE executive board meeting will be held in Albany at the De Witt Clinton Hotel on February 16 and 17. Following the dinner at the hotel on Monday evening there will be a visit to the legislature. On Tuesday at 9:30 A.M. the Executive Board will meet. They will recess at 12 o'clock for luncheon and resume at 1:30 o'clock. Let us make this a 100 per cent attendance. Keep the Convention dates in mind—April 27, 28, 29, and 30, 1942.

County News

Albany. The project for the year will be to present two Gatch beds to the Hospital for Incurables at Kenwood Heights.

Fulton. Donations were made for three worthy causes: \$5.00 to the Fulton County Health Society for Christmas seals, \$15 to the Red Cross Emergency Fund, and \$5.00 for the Fulton County Children's Committee's Christmas Fund. A resolution was adopted offering the services of the entire group to the Defense Council.

Nassau. A combined medical society and auxiliary meeting will be held on February 24 at the Cathedral House at 9:00 P.M. The speaker is to be Dr. Richard Brickner.

Onondaga. Fifty members were present at

the last meeting and heard Mrs. Ramona Baxter Bowden review several current New York plays. Mrs. Joseph R. Wiseman and Mrs. H. O. Brust presided at the tea table.

Queens. The last meeting of the auxiliary was held in the Medical Society building, with Mrs. William Godfrey presiding. The new members of the board were introduced. Three thousand hours of Red Cross work were credited to the auxiliary; a Red Cross Unit will be formed in February. Starting on February 10 a series of bridge parties will be held on the second Tuesday of each month.

Rensselaer. Congratulations to the newly elected president, Mrs. Eugene F. Connally.

Suffolk. The press and publicity chairman reports that a joint dinner was held with the doctors, the county being hostess to the other counties. Dr. Samuel J. Kopetzky, president of the New York State Medical Society; Dr. Joseph S. Lawrence, executive officer of the State Society; Dr. Luvia M. Willard, chairman of the American Woman's Hospital Reserve Corps, Jamaica, New York; and Mrs. George B. Adams, our own president of the New York State Woman's Auxiliary, were speakers at this meeting.

FARM AND HOME WEEK—CORNELL UNIVERSITY

Farm and Home Week will be observed at the College of Home Economics, Cornell University, Ithaca, February 9 to 13. The State Department of Health has been invited to participate and through its Division of Public Health Education has arranged the following program:

Tuesday, February 10, 10:00 A.M.—The Chairman is Dr. Dean Franklin Smiley, medical advisor, Cornell University. A symposium, "How Can We Make the Most of the School Examination?" will be given by Dr. J. G. Fred Hiss, Medical Society of the State of New York; Marie E. Swanson, R.N., supervisor of school nurses, State Education Department; and Dr. Robert Broad, health officer and school physician, Ithaca.

3:00 P.M.—"Diseases and Disease Conditions Caused by Poor Diets," by Dr. Raymond D. Fear, district health officer, Ithaca.

Wednesday, February 11, 10:00 A.M.—"The Nation's Treasure," by Dr. Elizabeth M. Gardiner, director, Division of Maternity, Infancy and Child Hygiene, State Department of Health.

11:00 A.M.—"What Is Wrong With Your Teeth?" by Dr. A. B. Dusenberre, Ithaca.

Thursday, February 12, 9:00 A.M.—"Personal Adjustment in the Middle Years," by Dr. Helen D. Bull, professor of home economics, Cornell University.

11:00 A.M.—"How the Public Health Nurse Protects the Rural Home," by Mary E. Donnelly, R.N., district supervising nurse, Ithaca.

Friday, February 13, 11:00 A.M.—"Health of the Family on the Farm," by Assemblyman Lee B. Mailer, chairman, New York State Health Preparedness Commission, Albany.

12:00 M.—"Symptoms of Cancer," by Dr. Louis C. Kress, director, Division of Cancer Control, State Department of Health.

A health education center will be set up in Room 266 of the College of Home Economics. Materials for use in community health education programs will be shown and a daily consultation service will be offered.

A physician is an unfortunate gentleman who is every day called upon to perform a mir-

acle—namely, to reconcile intemperance with health. —Voltaire

NEW YORK STATE JOURNAL OF MEDICINE

Copyright 1942 by the Medical Society of the State of New York

VOLUME 42

FEBRUARY 15, 1942

NUMBER 4

Editorial

We Are All in It Now

As this issue of the JOURNAL appears, the registration of all male citizens between the ages of 20 and 45 is taking place in the United States. This will affect even members of Local Draft Boards themselves who are under 45 years of age, as well as many thousands of physicians. All male physicians in this category are liable for military service and those who do not hold commissions are subject to induction under the Selective Service Act.

Every physician in this age group has been or will be asked to enroll with the Procurement and Assignment Service. He will thereby be certified for a position commensurate with his professional training and experience as requisitions are placed with the Procurement and Assignment Service by military and other governmental agencies requiring the assistance of those who must be dislocated for the duration of the national emergency. Civilian hospital staff services and civilian defense medical service will also be allocated among the medical profession from the P. and A. Service.

No other category of professional men to our knowledge has available the assistance which the Procurement and Assignment Service affords to medical men for the first time in this war. To facilitate the operation of the P. and A. Service, Dr. Arthur W. Booth, of Elmira, New

York, has been designated as chairman of the P. and A. Service for the Second Corps Area and Colonel Samuel J. Kopetzky, M.C., as chairman for the State of New York, with temporary headquarters in New York City at 292 Madison Avenue.

The Selective Service Law embraces a larger group than the one now registering—namely, those above the 45-year-old level. Under the law these will be required to register at a later date, be subject to the same rule as is now being applied to those below the 45-year-old level.

It may interest our members to know that the maximal age for an original appointment in the Army is 55 years. The maximal age for original appointment in the Naval Reserve is 50 years.

It must be obvious to all that the criteria for deferment from military service of physicians with dependents cannot be the same as for the layman of the same age having the same number of dependents. The doctor has the prospect of being a commissioned officer and his dependents can be supported on an officer's pay.

It must also be obvious from the above that only the physically disabled will be deferred. These, too, probably will be used by the government in other than military categories.

Yes, we are all in it now.

Advanced First Aid

In this issue of the JOURNAL will be found on page 355 special articles on emergency care of wounds, hemorrhage, and shock, transportation of fractures, abdominal injuries, head and chest wounds, and burns. In these days when nearly all physicians are instructing in first-aid classes or teaching advanced first aid, these articles by L. M. Thompson, M.D., Robert H. Kennedy, M.D., and Frederic W. Bancroft, M.D., delivered at The New York Academy of Medicine by arrangement with the Medical Society of the County of New York at the instigation of Dr. Condict W. Cutler, Jr., chief of Emergency Medical Service, Manhattan, should have great interest and instructional value.

The manner in which war is waged today is vastly different from that of previous wars. In the realization that our country has now embarked upon a vast program of offense and defense, the medical aspects of war assume an important place in the minds of civilian physicians who will be called upon to bear the brunt

of the work. We shall use every means available to keep the physicians of this state informed of current war medicine and surgery. In this war every one must serve in some capacity.

Information concerning chemical (gas) warfare does not seem to be available so far to the physicians of the state in compact form. We are therefore the more fortunate to be able to present in this issue on page 350, a condensed, but highly informative special article on this subject by Dr. W. J. McConnell, assistant medical director of the Industrial Hygiene Laboratory of the Metropolitan Life Insurance Company.

Doubtless, in time, the Office of Civilian Defense will distribute generally its booklet *Protection Against Gas*, prepared by the War Department in December, 1941. In the meantime, every physician in the state who keeps handy this issue of the JOURNAL will have available for his own information or for the instruction of others essential information on this subject.

Medical Licensure Examinations

On January 16, 1942, according to advices reaching us from Albany, the State Board of Regents ratified the action of the commissioner, Dr. Ernest E. Cole, who suspended a requirement relating to medical licensure examinations.

Apparently, Dr. J. Hillis Miller, "associate commissioner in charge of higher education, had suggested to Dr. Cole," according to the *Albany Times Union* of January 17, 1942, "the temporary abrogation" of the licensing rule to "make it possible for a number of individuals trained in medicine to become more readily available for defense activities with the armed forces, or among civilians."

The requirement relating to medical

licensure examinations which Dr. Cole suspended and which suspension the State Board of Regents ratified is apparently that one having reference to licensing examinations: special requirements, (a) Medicine,¹ approved December 20, 1935, and amended May 20, 1938, and January 19, 1940. The section provides in part that: "The examination shall be held three times each year at times and places that shall be determined by the Commissioner. Application shall be filed with the Department not less than fifteen days before the examination. The subjects of the examination shall be:

¹ Handbook No. 9, University of the State of New York, June, 1941, pp. 13-14.

Group 1—Anatomy; physiology; chemistry.

Group 2—Hygiene; surgery; obstetrics and gynecology; pathology; bacteriology; diagnosis.

"A candidate who fails in more than one subject in either group shall be re-examined in the entire group.

"A candidate may be conditioned in one subject of each group and may remove these conditions at any other subsequent examination. Any candidate who has written three examinations, except examinations for the removal of conditions, and who, after the third examination, *has failures in at least two subjects in either group, shall not be eligible for re-examination for a period of one year*"²

A correspondent, commenting upon this action of Commissioner Cole writes: ". . . . the Regents on last Friday suspended this requirement of waiting a year and will hereafter permit applicants to continue to repeat their attempts any time an examination is set until they finally pass. . . . It is really conceivable that those with little knowledge could prepare themselves in one or two subjects, enter an examination, pass those and fail all the others, and then for the next examination prepare themselves in one or two more subjects and thus, finally, achieve their goal In my opinion, this action very definitely lowers the standard of medical education. . . ."

Our correspondent's opinion is, of course, his own. The whole question of medical licensure in this state is naturally of vital importance to the entire profession. When changes in licensing provisions are made, it affects in one way or another every physician.

Dr. J. Hillis Miller at whose sugges-

tion, according to the *Albany Times Union*,³ the change was made is not a physician. He is an M.A., Ph.D., Litt. D.

Dr. Ernest E. Cole is not a physician. He is an LL.B., Pd.D., LL.D.

The Board of Regents which ratified the action of the Commissioner consists of twelve members of whom one only, Dr. Grant C. Madill, is a physician.

That the change in the requirements relating to medical licensure may have a profound effect upon the practice of medicine in the state is evident. That the change has been proposed, accomplished, and ratified by an official group comprising only one physician will raise the question in the mind of every physician whether the health interest of the public has been adequately considered. We note that Dr. Miller suggested the change to Dr. Cole on the ground that it would make it possible for a number of individuals trained in medicine to become more readily available for defense activities with the armed forces or among civilians.

Our interest naturally is not primarily with the "number of individuals" but concentrates on the phrase "trained in medicine." How *well trained in medicine* is this "number of individuals" for whom it becomes necessary to abrogate certain licensing provisions in order that they may enter into the practice of medicine and surgery in the State of New York?

Are we really so short of competently trained physicians, licensed in the usual manner, as to make this necessary? The medical profession is profoundly interested, being concerned with the quality, as well as the quantity, of medical service in the state.

² Italics ours—Editor.

³ *Albany Times Union*, Jan. 17, 1942.

Straight Thinking

In his inaugural address to the Medical Society of the County of New York, Dr. Maximilian Ramirez, on January 26, 1942, said, in part:

"The first matter I wish to discuss is the protection of our fellow doctors who have been or may be called to the colors. Many of them, especially the older men, in entering upon active duty with the armed forces of our country, will in their patriotism leave lucrative practices built up by years of constant service. They need to be protected lest the hard-won fruit of years be snatched from them in their absence by men who either do not share their patriotism or, being ineligible for active service and remaining at home, will proceed to plow in another's field and batten on what should be another's harvest. The solution of this problem is not easy. I ask that you give it careful thought so that we may promptly arrive at a satisfactory decision."

We feel that this matter is indeed one calling for serious and conscientious study. Particularly is this true in view of the fact that at this time men between 20 and 45 years of age are being called. The situation and problems of physicians in the age group 35 to 45 is particularly grave because of their usually heavy commitments with respect to real estate, insurance, and dependents. It is, we believe, a problem that each locality and each county society will have to consider and solve as best it can, locally. Certainly, as Dr. Ramirez remarks, it is a question now calling for prompt action.

"A word here about women physicians. They have attained an enviable and honored position in the medical profession and can make contributions of real value to our county society. In the last World War they did valiant work, and they are not wanting in our present crisis. It seems proper then to invite and encourage them to take a more active part in the affairs of their county society. Our women physicians have long complained, and with justice, of the segregation policy adopted against them, particularly by the hospitals. This would be a challenge in normal times but is an exacting challenge today. Every doctor, man or woman, will be needed in the hard days that lie ahead. Moreover, in the event

that the drain on hospitals becomes acute because of current military needs, hospitals would act wisely to rearrange their facilities so that women doctors can replace the men as interns and residents, and thus allow the hospitals to continue to adequately serve civilian medical needs. We must no longer make our women doctors feel that they are unwelcome intruders into the profession."

Many will have read the letter by Dr. Emily D. Barringer, president, American Medical Women's Association, which appeared in the January 15, 1942, issue of the JOURNAL. In it she asks why women physicians are ineligible to the Medical Reserve Corps, "at a time when there is an advertised shortage of physicians in the Medical Reserve Corps of between 1,000 and 2,000?"

Without entering into the merits of her argument, it would seem to us that the probable shortage in civilian physician personnel will be far greater than that of the Medical Reserve Corps and that, as Dr. Ramirez sensibly suggests, "every doctor, man or woman, will be needed in the hard days ahead." In his address before the New York County Medical Society, Mr. Paul V. McNutt, Federal Security Administrator, said: "The Procurement and Assignment Service has expressed the desirability of retaining in essential positions those physicians, dentists, and veterinarians over the age of 45, women physicians, and those under the age of 45 whose physical qualifications do not meet the standards for commission in the military services."

Hospitals would indeed do wisely we feel to rearrange their facilities so that women doctors can replace men as interns and residents; it seems merely logical.

Of South America and its physicians there is a most pertinent comment.

"May I ask you now to turn from internal and local problems to a rare opportunity which is at hand to encourage better relationship with our South American friends both medical and lay? This opportunity awaits all the United States, but particularly New York. I say New York in particular because

it is the largest and most thickly populated city in the country and should have the best hospital and teaching facilities to offer to our visitors from South America. . . . With all our hospitals, with all our teaching institutions, our postgraduate instruction is comparatively poorly organized, and the average doctor arriving in New York is often at an utter loss as to where to go or to whom to go for advice and instruction. He may enroll for a course at some hospital or other institution that advertises postgraduate courses. What then? He is often required to enlist for a time entirely too long for the average physician who does not want to go through his entire medical school training again. He wants merely to learn some of the things that we here in New York with our vast population and exceptional opportunities may know about, and may be able to give to him, so that he will return to South America with much additional up-to-date medical knowledge. Moreover, he is required to pay an extremely high fee, for we do not realize that the rate of exchange between this country and many of the South American countries is such that the fee which we charge for a six weeks' course may be more than is charged at their home for an entire four- or six-year course of instruction."

While this suggestion applies to the medical facilities of New York City principally, the matter is one which deserves immediate consideration in view of the diplomatic conference now being held in South America as a result of which

many countries there have severed relationships with Europe. We have a responsibility in this severance which goes beyond a mere Pan-American war alliance.

Finally, "We place ourselves, our medical knowledge, our experience, our skill, and all our resources at the disposal of our President, the Commander-in-Chief of our Armed Forces. In him we place our full trust; and it is for him, not for us, to decide when and how we shall serve. I would counsel strongly against all attempts to form small groups for various and sundry minor emergencies that fall within the framework of the one, great, all-out emergency. There are and will be inadequacies, gaps and shortages, but individual attempts to fill in such open spaces may in the long run seriously impede progress. Self must be inexorably subordinated to the whole and we must all be satisfied to sacrifice individual recognition and act as a united whole. We must guard against emotionalism and misguided individual enthusiasm.

"But while professing our complete patriotism, we bluntly caution the federal, state, and city governments and all privately sponsored movements that though they can count on every bit of assistance and cooperation from the medical profession that is required by our government during this grave emergency, we shall be quick to detect any attempt to saddle the profession with changes in our present form of practice under the pretext of national emergency."

Runyon on the Doctor

In the column conducted by Damon Runyon¹ entitled the "Brighter Side," there appears an opening sentence: "The next time you see your doctor, feel sorry for him. He is the most neglected of all citizens, though no one will deny that he is the most valuable." Mr. Runyon continues in his exposition of what is *not* done for the physician. The doctor is the one individual whose services are available at all times regardless of economic sacrifice. With regard to his future, there is no provision made for him or his family in the program of Social Security.

What is ordinarily considered by the laity

as Organized Medicine in no way corresponds to unionization. Banded together as doctors are to protect the welfare of the public against exploitation and charlatanism, they would vote unanimously against any "strike" even though it might affect their economic well-being.

We cannot improve upon Runyon's comments. "We can just imagine the stir an organization of that nature would create throughout the land. There would be a great outcry, indeed, if the doctors decided they needed a union to better the conditions of their profession, say with reference to hours and compensation and pensions and working conditions in hospitals and elsewhere

¹ Runyon, D.: *Daily Mirror*, October 13, 1941.

and to regulate the amount of service they render the public free of charge and to bring about a little more promptness in the settlement of bills among patients able to pay. It would be quite a spectacle to see a committee of distinguished union doctors picketing the premises of some notorious nonpayer of medical fees."

The doctor, a member of Organized Medi-

cine, seeks no security through his membership. It seems silly, but his affiliation with Organized Medicine represents his desire to fulfill to the utmost his obligation to society. We earnestly hope that Damon Runyon represents the forerunner of the host of patients who vocally will support the continuation of the American system of medical practice.

Lest We Forget

The remarkable advance in the treatment of medical and surgical disease has exceeded all expectations of the medical profession. What has been accomplished in the short space of two decades has resulted in the further relief of suffering and the prolongation of life expectancy.

Chemotherapy, particularly the use of the sulfonamide products, has eradicated the threat of hitherto incapacitating and sometimes fatal disease. The complications of gonorrhea in the male have been reduced so materially by the use of this chemical that the crippling results of neisserian arthritis are becoming less and less evident. The meningitis following nasal and otitic infections, which were, in the past, attended with a mortality of almost 100 per cent, now no longer hold out a fatal prognosis.

Serum and vaccines, too, have been efficacious in the irradiation of diphtheria, tetanus,

and typhoid, and there is a promise that scarlet fever and pertussis may be eliminated by the use of these agents. Certainly in pertussis, the Sauer vaccine has proved its value in contracting the course of the disease and in the lessening of complications.

With this rapid advance in specific therapy it is too easy to overlook the importance of symptomatic treatment. Sedation is still important for the patient's comfort. The intrinsic role of the opiates seems to be lost to our novitiates in medicine. The cold pack, the ice cap to the head, and the hot-water bottle have been relegated to the nurse. We could go on enumerating many other therapeutic aids that are all too familiar to the so-called "horse and buggy" doctor. They still merit substance in the practice of medicine, and creditably so. Those of us who treated the wounded in World War I know how much was accomplished by giving a wounded soldier a cigarette.

Our Nurses

The demand for nurses in our defense program has caused both the Army and Navy to issue urgent appeals for enlistment in this branch of the Medical Corps. The young ladies are commissioned and hold rank equal to a second lieutenant, and when all expenses are deducted they are left with \$70 free and clear.

The pay for nurses, which can be considered as an average throughout the country, is \$80 a month and full keep for institutional work. Those who live outside of the nurses' home are given a few dollars more per month. The various positions now open for nurses in the industrial field have increased materially. Furthermore, their skilled training has enabled many of them to fill successfully factory and machine jobs that pay them comparatively high wages.

The scarcity of nurses for hospital work is now becoming an acute problem. The lure of higher paid jobs is depleting our wards of highly trained nursing aid. Replacement is not easy, and our married nurses are either not too willing or cannot assume obligations outside of their own households. They may (and they can always be depended upon) be induced to help out during a temporary shortage in the hospital that gave them their training. They will not, however, continue this indefinitely.

If we are to keep our nurses whom we have trained for special service in the community that the hospital serves, we must be prepared to meet financially all inducements that other fields offer. Our girls would much rather stay with us; they know us and like to work with us. But \$25 a month more on the pay

check is an almost insurmountable handicap. It is our opinion that some raise in pay, no matter how small, will keep our nurses happy

in the positions we have created for them. Hospitals, and physicians also, must give this problem serious consideration.

Correspondence

War and the Woman Physician

To the Editor:

Inasmuch as Dr. Emily D. Barringer has written a letter to the men physicians of New York State, which was published in your number of January 15, 1942, requesting them to write to the heads of the Military Services urging the appointment of women physicians to active service in the Army and Navy, I think we are entitled to ask the women physicians a few questions.

Are they aware that a considerable part of the duties of a Medical Officer in the Services consists in the inspection of the men for venereal disease and the treatment of such disease when discovered? Are they ambitious to assume this duty? And if so, do they imagine that the soldiers will enjoy their ministrations?

Or do they expect to be a privileged and more

or less ornamental part of the Army and Navy, protected and coddled, while the men physicians perform the hard and disagreeable jobs?

The mobility of the services personnel, and their at least theoretical ability to perform any duty to which they might be assigned, is an essential requirement, especially in time of actual warfare. Also the matter of accommodation in quarters would present some pretty problems.

We should appreciate an answer to some of the above suggested questions before we go all out for the appointment of women physicians to the Services.

Yours fraternally,

E. C. McCulloch, M.D.
Lt. Col., U. S. Army, M.C., Retired

January 23, 1942

To the Editor:

In answer to the letter of Lt. Col. E. C. McCulloch, U. S. Army, retired, I would say that I consider it of the utmost importance to get down to a discussion of any possible basic reasons why women physicians should not be eligible for the Medical Reserve Corps of the United States Army and Navy and he has frankly stated where he sees the greatest difficulty—namely, in connection with the venereal diseases.

Before answering this question I wish to draw attention to the fact that I am referring to the Medical Reserve Corps and not the Medical Corps.

Quoting from (35 Stat. 66) April 23, 1908: "An act to increase the efficiency of the Medical Department of the United States Army" it states "that for the purpose of securing a Reserve Corps of Medical Officers available for Military Service, the President of the United States is authorized," etc. This Medical Reserve Corps, as I understand it, is made up of physicians who in peace time do civilian practice, and after the National emergency return to civil practice. Furthermore, I understand that the Medical Reserve is divided into two classes. The Volunteer General Reserve Officers are doctors under 35 years of age who are eligible to perform all the general duties of the regular Medical Officers; doctors who have recently graduated may join this group with rank of Lieutenant. Then there are the Volunteer Specialist Reserve Officers who are under 50 years of age and who have Specialist rating. They are given rank up to Lieutenant Commander depending on their experience and age. The specialties represented

are Surgery, Orthopedics, Ophthalmology, Otolaryngology, Radiology, Internal Medicine, Neuropsychiatry, Urology, and Pathology.

This Nation is facing the most devastating war of its entire history. It has been widely advertised throughout the land that there is an acute shortage of doctors. Have we been misinformed on this point or is it so? Where and how can the patriotic woman physician give her best? The vast majority of women physicians will find themselves doing civilian practice or home defense work. But there are a goodly number who are eligible for the Medical Reserve Corps as to age and health, are unattached, and want to find themselves with proper military rating. Again the majority of these women applying would come in the specialists' group. Would this group of specialists be called upon to examine a lot of young fellows who may or may not have contracted venereal disease? And so, in answering Dr. McCulloch, I feel that the problem of venereal diseases does not affect so large a group as he implies and is probably confined to the Volunteer General Reserve Officers under 35 years.

I believe any young woman physician applying in this General Reserve Officer group should be well informed and skilled in genitourinary surgery and the diagnosis and treatment of venereal disease. Fortunately, this training is not hard to get these days when this nation-wide campaign against venereal disease has swept the country. While it is to be hoped that the Army and Navy will not unduly overrate the importance of venereal disease and offset the value of a woman physician in other fields, my answer is,

if she must treat venereal disease, let her go to it and take it in her stride.

As to the question, "do they imagine the soldiers will enjoy their ministrations?" I can answer how I believe they will react, based on my own personal experience. In 1902 I found myself in a unique position as being the first woman intern appointed on a general mixed service in a city hospital with a heavy ambulance service (Gouverneur Hospital, New York City). The majority of the patients were men from every walk of life—soldiers, sailors, longshoremen, hucksters, gangsters. I knew I should run into this very problem of genitourinary work and I was well prepared for it. Thanks to my professor of urology I had acquired more than usual skill in treating various types of cases. I learned one lesson early and that was that the physician who was most skillful was the one who was in greatest demand. During a two years' service (in which I progressed to House Surgeon) I ran the full gamut of genitourinary surgery and the venereal diseases, and I can truthfully say that never once in thousands of cases did I have any trouble with a male patient. They were at all times respectful and grateful for what I tried to do. I had no trouble with the orderlies or on the ambulance where I handled hundreds of cases. All this was possible because I was in a position of authority, with power to have my orders obeyed. I did, however, meet with great opposition on the part of some of my fellow staff mates. I wonder if history is going to repeat itself? All this happened forty years ago. Since then many other general hospitals have been opened to women physicians. The male venereal problem has been adjusted, in justice to everyone concerned.

The Army and Navy could also adjust this problem if they so willed.

It is just possible that a skillful and up-to-date woman physician might have a salutary effect on the young infected fellows in our camps and hospitals. Surely, at the present moment the Army and Navy are in no position with their rising venereal disease incidence rate to say that this would be impossible.

With regard to the women physicians expect-

ing to be "a privileged and more or less ornamental part of the Army or Navy," I can assure Colonel McCulloch that this taunting remark is quite unnecessary and entirely out of keeping with the American woman physician's feeling. She thinks in possibly the opposite direction and believes that the men physicians are leaving the women physicians to perform "the hard and disagreeable jobs" while they receive the military rating, better salaries, fuller protection. I believe Col. McCulloch will find that the woman physician is quite equal to her brother in hard work, endurance, and loyalty and, if circumstances are such that she must shift quickly from one type of work to another, she will be as able as he in making the change.

As to the question of accommodations for women physicians, this surely is one feature that can be corrected *now*, while these huge sums of money are being expended in building new hospitals and camps. Every such building should be planned to accommodate a mixed staff of officers.

And so I would say to Colonel McCulloch and his friends, we are in the midst of a terrible national emergency; remember that a skillful physician, man or woman, is not developed overnight. It takes long years of hard work, self-denial, and often hardship. If there is an outstanding woman surgeon who applies, take her. If another woman can do fine plastic surgery, take her. If another is an authority on contagion, take her. Don't lose the value of these experienced skillful women because some of the younger group may have to thrash out the venereal disease problem and incidentally may show us older folks newer and better ways to do it.

The women physicians want to truly work shoulder to shoulder with their brothers and have all sex discrimination put aside. We are all physicians together in this terrific struggle to help win this war. I appeal to Colonel McCulloch and his friends to help us. I shall be glad to answer any further questions that I can.

EMILY DUNNING BARRINGER, M.D., *President,*
American Medical Women's Association

It isn't too early....

....to make your reservations for the 1942 Annual Meeting: April 27-30, New York City. Headquarters will be at the Waldorf-Astoria Hotel. The program is one that you will *not* want to miss.

SURGICAL INTERRUPTION OF THE PALLIDOFUGAL FIBERS*

Its Effect on the Syndrome of Paralysis Agitans and Technical Considerations in Its Application

RUSSELL MEYERS, M.D., F.A.C.S., Brooklyn

IN HIS 1928 monograph on the complications and sequelae of encephalitis lethargica, von Economo⁵⁷ lamented the fact that the therapy of the chronic stage is the saddest chapter of epidemic encephalitis. In the decade that has passed since this was written, a wide variety of therapeutic agents, including pharmacologic, dietary, psychologic, and physical therapeutic measures, has been employed in the effort to deal with the distressing late manifestations of encephalitis.^{25b, 25c} Particular attention has been directed to the commonest and most disabling of these sequelae—namely, parkinsonism. Although some encouraging results have been reported following the use of certain new agents—e.g., cobra venom,^{12a} vitamin B₆,^{13a, 13b, 53} syntropan,⁴⁹ metrazol shock therapy,⁶² benzedrine sulfate,^{4, 9, 36, 41, 58a} and bulgarian belladonna root^{7, 8, 12b, 15, 27, 35a, 35b, 36, 38, 56a, 56b, 58b, 59}—and by the more intensive application of certain of the older agents—e.g., atropine^{1, 6}—the statement made by von Economo appears at present to be in no serious need of revision.

Under the best of circumstances these therapies are symptomatic rather than curative, and as such they require to be administered throughout the lifetime of the patient. Unfortunately, their effects on the disease process are unpredictable from patient to patient, and “relapses” frequently occur even in those patients initially considered to be improved.^{56a, 56b} Moreover, excepting vitamin B₆, the drugs referred to exert untoward side reactions. In view, therefore, of the necessity of sustained administration and high dosage, contraindications are numerous.^{33, 40, 51} Finally, the least conspicuous benefit is exerted by these agents on the very symptom that above all others is the one from which the parkinsonian patient seeks relief—namely, tremor.^{4, 7, 8, 12b, 27, 35a, 35b, 38, 41, 45, 56a, 56b}

By contrast with patients afflicted by many other chronic diseases of the brain, the sufferer from postencephalitic parkinsonism is characteristically relatively young and usually possessed of an intact intellect. This makes his plight the more distressing, for under the present limitations of therapy he is faced with a lifetime of serious physical, social, and economic incapacities. The psychologic reactions that commonly develop in relation to such a frustrating disease are as understandable as they are apparent.

The recognition of these facts and of the generally disappointing character of the more conservative modes of therapy has prompted recent efforts to deal with the problem by surgical means. Certain observations (not the least significant of which is that parkinsonian tremors and rigidity are regularly abolished in limbs paralyzed by virtue of a supervening cerebral apoplexy) appear to justify the conviction that there exist, in fact, discrete neural pathways that subtend the clinical manifestations of paralysis agitans. That these pathways constitute highly complex circuits running through essentially all levels of the nervous system can scarcely be doubted.^{31c} In view of these premises, the problem of surgical therapy in parkinsonism becomes, in essence, one of interrupting the postulated neural circuit at some convenient point. Ideally, this interruption should entail no damage to those structures upon the integrity of which motor, sensory, coordinative, and intellectual functions depend.

To devise a more specific surgical procedure on a rational basis is difficult for a number of reasons. A review of the physiologic, pathologic, and pathogenic considerations relevant to paralysis agitans makes it clearly evident how inadequate our comprehension of these important issues is. Here, as elsewhere in medicine, the coexistence of numerous rival hypotheses^{2, 11, 12, 14, 16a, 16b, 17, 19, 20, 22—24, 25—30, 32, 32, 39, 46, 47, 50, 52, 54, 55a, 55b, 60a, 60b, 61} is, in itself, an index of the grave deficiency of factual knowledge which at present obtains. A further difficulty in the resolution of the surgical problem is referable to our inability to reproduce in laboratory animals the clinically encountered syndrome of paralysis agitans.

Awarded the Lucien Howe Prize in Surgery at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Department of Physiology (Neurophysiology), Long Island College of Medicine, and the Neurosurgical Service of the Kings County Hospital.

* In the interest of space conservation for the purposes of publication the original article has been abstracted and 9 of the illustrations have been deleted.

The earliest surgical procedures employed against postencephalitic parkinsonism consisted of general measures directed against focal infection and orthopaedic measures for the correction of muscular contractions and bony displacements.^{25a, 25b} Occasional efforts have been made to alleviate the symptoms by altering the endocrine balance.³⁴ Peripheral neurectomy, sympathetic ramiectomy, and/or ganglionectomy, and dorsal rhizotomy are representative of the earlier surgical attacks on the nervous system itself. If one may judge from the recent literature, these "peripheral" procedures have been largely abandoned.

During the past ten years the attention of surgeons has been directed at the central nervous system. Puusepp^{43a, 43b} and Rizzatti and Moreno⁴⁵ reported their inability to influence favorably the tremors of parkinsonism by section of the dorsal columns. Putnam^{42a-d} employed anterolateral chordotomy in 5 successive cases of unilateral parkinsonian tremor and reported failure in each instance. The experiences of Foerster and Gagel⁴⁰ and of Oldberg³⁷ with this procedure were similar to that of Putnam. Mashanskiy,^{25c} however, reported 8 successes among 17 cases in which he employed Putnam's operation. The reason for the discrepancy in these results is not apparent from an examination of the original articles.

Putnam^{42b} obtained substantial relief in 7 cases of unilateral paralysis agitans by interruption of the homologous lateral pyramidal tract at the second cervical segment. It is worthy of note that the motor disability resulting from this operation is far less than would be expected to supervene if the functions traditionally imputed to the pyramidal tracts are validly posited.

The single recorded attempt to deal with the symptoms of parkinsonism by operation at the level of the cerebellomesencephalic complex is that of Delmas-Marsalet and van Bogaert.⁵ In their operation the dentate nucleus was surgically damaged. The rigidity factor was favorably influenced, but the tremors were severely intensified and, in addition, were complicated by the appearance of ceaseless torsion spasms.

Several authors have reported upon the results of cortical extirpation of portions of Brodmann's areas 4 and 6. Bucy and Case^{3a} obtained an enduring abolition of rhythmic movements in a patient suffering from a post-traumatic unilateral tremor. In a second case of unilateral parkinsonian-like tremors

of uncertain origin (possibly syphilitic), Bucy^{3b} recorded a similar success. The permanent residua of these operations have been reported as apraxia, a moderate degree of paresis, bradykinesia, and ataxia of the affected extremities. Putnam obtained considerable improvement in an instance of post-traumatic unilateral tremor by resection of a portion of the precentral gyrus.^{42c} The resulting motor disabilities (dyspraxia and paresis) were considered by this investigator to be greater than those resulting from his operation of interruption of the lateral pyramidal tract in the cervical cord. In 2 additional cases of unilateral paralysis agitans (more readily comparable with the postencephalitic type than his first case) Putnam was unable to alter appreciably the symptoms by resection of a portion of area 6. White^{42e} employed the same procedure in a single case and obtained only partial relief. Klemme appears to have had the widest experience with this operation. A number of highly favorable results has been indicated in brief preliminary reports by this worker,²¹ but the protocols of his cases of paralysis agitans have not been published in detail as yet so that a precise evaluation of the neurologic and psychologic sequelae of the operation in Klemme's hands cannot be made at this time.

In other reports the writer^{31a-c} described the effects on the several symptoms of parkinsonism produced by surgical procedures on the basal ganglia. In the first 4 cases the head of the caudate nucleus was extirpated, and certain of the extrapyramidal and corticopetal fibers coursing in or toward the anterior limb of the internal capsule were interrupted. Alternating tremors were favorably influenced in all of these cases,* but the symptoms consequent upon the factor of rigidity were benefited to a less appreciable degree. In the next 2 cases extirpation of the oral parts of the putamen and globus pallidus was carried out in addition to the procedures of ablation of the head of the caudate nucleus and section of the fibers in the oral three-fourths of the anterior limb of the internal capsule. The tremors were effectually abolished in both these patients, and the rigidity factor

* One of these 4 cases, after an initial improvement lasting three and one-half months, later had to be classed as a failure by virtue of a slow recurrence of his tremors. The patient was a chronic alcoholic who had, in addition to his parkinsonian-like symptoms, clinical evidences of cortical and cerebellar disease. There was no history suggestive of encephalitis. The experience provided by this case indicated the necessity of avoiding the selection of this type of patient in the future. Improvement in the other 3 cases has been sustained.

was markedly improved although not entirely eliminated. The first of the 2 latter cases was freed of a severe festination; the second, of a dragging limp of the right leg. This operation, however, was considered to carry undue risks from the standpoint of recovery of motor function, particularly since a number of small arteries of supply to the genu and posterior limb of the internal capsule traverse the bed of the putamen. It was therefore abandoned in the next 3 cases of the series in favor of an interruption of the pallidofugal fibers. This procedure, in the light of subsequent observations, appears to be the most effective of the several operations employed at the level of the basal ganglions. The alternating tremors were abolished or were rendered barely perceptible, and rigidity was effectually reduced with a consequent prompt improvement in the symptoms of akinesia, bradykinesia, flexor posture, dysarthria, and deficiency of automatic associated acts. Inasmuch as these effects have been described elsewhere in my protocols,^{3,10} no attempt will be made in the present communication to review them. It is to be indicated, however, that the operation of interruption of the pallidofugal fibers may be carried out without producing any clinically determinable impairment of sensory, motor, reflex, coordinative, eupractic, and intellectual functions. This is perhaps its chief virtue. Furthermore, it is a relatively simple technical procedure and is capable of fairly precise standardization by virtue of the clear-cut delineation of the anatomic landmarks involved. In this respect it enjoys a small advantage over the operation of cortical extirpation, since the latter entails the arduous task of identifying the excitable motor cortex by electrical stimulation, of estimating by gross inspection the extent of area 6, and of taking the irregularities of cortical circulation into consideration in planning the surgical resection. Finally, interruption of the pallidofugal fibers is almost as bloodless in the crucial maneuver as chordotomy and appears to be applicable to bilateral, as well as unilateral, cases of paralysis agitans.

My previous communications were addressed primarily to neurologists and neuropathologists, and for this reason a precise description of the surgical issues at hand was not included in the protocols of the cases. In view of this it is intended in the present paper to set forth in some detail the technical considerations relative to the procedure of

pallidofugal section. In addition to describing the operative technique, it appears desirable in this communication to consider the factors of significance in the selection of the patient for surgery and to indicate the more important procedures implicit in the clinical work-up of the surgical patient.

I. The Selection of the Patient for Surgery

The broad principles that guide the application of elective operative procedures in general are applicable here. In brief, the patient's physical condition must be such as to promise that he will withstand major cerebral surgery. The condition of the heart, lungs, liver, and kidneys and the general nutritive state of the patient require preoperative evaluation by the routine methods of examination and, where indicated, by special tests. Although chronologic age is of less consequence than physiologic age, it would rarely appear justifiable to employ an operation of so serious a nature in an individual beyond the age of 50 or 55 years.

In every instance the candidate for surgery should be subjected to a period of observation lasting several months, during which time the effects exerted on his various signs and symptoms by the standard conservative medical regimens may be precisely determined. Especially desirable are trial periods on the belladonna derivatives and vitamin B₆. Physical therapeutic measures should also be employed during the trial period either separately or in combination with the pharmacologic agents. Accurate clinical records, supplemented whenever possible by motion pictures, are indispensable to the proper objective evaluation of the subject's preoperative status and the results of operation.

The patient's disease process should have been present for a period of sufficient length so that its nature is capable of reasonably accurate determination from the clinical standpoint. The duration of the parkinsonian symptoms in the 9 patients of my series was as follows: Case 1, seven years; Case 2, one year; Case 3, eight years; Case 4, six years; Case 5, eighteen years; Case 6, five years; Case 7, ten years; Case 8, twenty years; and Case 9, eighteen years. It is of significance that the single failure in the series was that of Case 2, a patient for whom operation would probably have been considered inappropriate if his disease process had been evaluated as now recommended. In the last analysis it is the responsibility of the surgeon to identify and avoid operation for conditions

such as early progressive lenticular degeneration (Wilson's disease), atypical Huntington's chorea, Vogt's disease, and Strümpell-Westphal's disease, which for a part of their early course may simulate paralysis agitans. Patients who disclose a fair degree of stabilization of symptoms or in whom the progress of the disorder is relatively slow appear to be the more favorable surgical candidates. In any case, if clinical evidence of a widespread implication of the nervous system is at hand, operation should be withheld.

Certain considerations referable to the patient as a personality have seemed to me to be of more than passing significance. The facts relative to the operation having been made known, the procedure should be actively sought by the patient rather than urged upon him. Experience indicates that the more severely afflicted patients are usually attitudinally set to petition for any procedure that offers a reasonable promise of relieving them of their tremors and rigidity. The likelihood of a successful therapeutic outcome is not as yet bright enough to warrant strong recommendation for those who can carry on in spite of their affliction. The patient ought to be possessed of a cooperative temperament so that the surgical procedure may be carried out under local anesthesia, and his intellectual status should be effectually normal so that re-educative and rehabilitative measures that may be indicated after operation may be entered upon with a reasonable expectation of realization. Lastly, it should be established that the patient possesses a degree of social stability such as will make a proper follow-up feasible.

II. The Clinical Work-Up

It has been a matter of routine practice to record preoperatively a number of somatic and vegetative functions so as to cover the possibilities of their derangement by the operative procedure. The approach to the basal ganglions by way of the cortex of areas 6 and 8 and the close proximity of certain hypothalamic nuclei (and their related pathways) and of the optic tracts to the site at which the pallidofugal fibers are interrupted require that particular attention be given to the pre- and post-operative states of the functions imputed to these structures.

The clinical history is recorded in detail, and a careful physical and neurologic examination is carried out. The grips are measured by the dynamometer. The visual acuity of each eye is determined (with and with-

out lenses), and the visual fields are plotted by perimetry. The eupraxic functions in particular are precisely described and, whenever feasible, are recorded cinematographically. The standard test that I use for this purpose is that of clasping and unclasping a safety pin, each hand being used separately and unaided by its fellow. The level of the subject's intelligence quotient is determined by administering the 1937 Stanford Revision of the Binet-Simon test and the Bellevue Adult Scale. In special cases the Pinter-Patterson Performance Scale is utilized. The vegetative processes of the patient are examined by the following means: skin temperature readings of corresponding points of the body from right to left; records of the fluid intake and output for three days under conditions of a standard diet; determination of the basal metabolic rate (often difficult of accomplishment because of the tremors); routine urinalysis; estimation of the blood nonprotein nitrogen, creatinine, cholesterol, and urea and of the serum calcium, phosphorus, and phosphatase. The foregoing studies are repeated from time to time during the postoperative period. The red and white corpuscles are examined and the level of the hemoglobin is determined. The blood group is likewise determined preoperatively in anticipation of the need of transfusion at operation. A Wassermann test of the blood serum is made. Electroencephalographic and electromyographic tracings are recorded preoperatively and postoperatively. Pneumoencephalography is carried out mainly for the purpose of estimating the size and position of the ventricles but also to disclose the presence, if any, of a midline tumor. It is rare that the syndrome of paralysis agitans is associated with a cerebral tumor, yet my attention was recently called to the case of a middle-aged machinist who had been treated at reputable neurologic clinics over a period of ten years as an instance of progressive hemiparkinsonism. Death occurred suddenly, and a hitherto unsuspected oligodendroglioma of the septum pellucidum impinging upon both caudate nuclei was disclosed at necropsy.

The pressure of the cerebrospinal fluid is recorded as a preliminary to the procedure of pneumoencephalography, and a sufficient sample of the fluid is saved so as to provide for a cell count, a total protein determination, a Wassermann test, and a colloidal gold curve determination.

At operation it is desirable whenever feasible to record the cerebral electrical potentials

directly from the cortical surface. A method of carrying out this procedure has been reported in a previous communication.^{31d} After exposure of the caudate nucleus, the electrical potentials of this structure may be picked up by means of an ordinary coaxial electrode of the Adrian-Bronk type. It is to be conceded, of course, that the data obtained by electrophysiologic methods are at present of small practical value in these cases. Nevertheless, the acquisition of such information is desirable because of its possible future significance. Tracings thus far obtained and reported elsewhere^{31e} suggest that (1) the cerebral cortex of the premotor area is an integral part of the tremor-mediating mechanism, or at the least that the neural activity of the tremor-mediating mechanism is projected onto the cortex, and (2) that the caudate nucleus itself neither initiates nor mediates alternating tremors, although it may, when intact, facilitate their appearance.

III. Technical Considerations of the Operation of Interruption of the Pallidofugal Fibers

The patient is secured to the operating table in the usual manner and, the head end remaining the highest, the table is tilted at an angle of approximately 23 degrees. By this means the drainage of venous blood from the head is facilitated by gravity. An intravenous infusion of physiologic saline solution is introduced through a cannula tied into the great saphenous vein at the ankle. A competent observer posts himself under the operative drapes in order to report upon any alterations in the patient's clinical picture that result from the operative procedures.

The scalp is prepared in any suitable manner. Under local novocain anesthesia a small skin flap, the base of which measures approximately 6 cm., is outlined. The medial arm of the incision corresponds to the sagittal line and begins a short distance below the hairline. It courses directly backward for approximately 5 cm., then sweeps laterally and arches forward so as to correspond roughly to a projected line separating area 6a α from area 6a β . From here the incision runs along the upper temporofrontal region and terminates at the hairline. The lateral arm is approximately 1 cm. below the superior margin of the fan of the temporal muscle (Fig. 1). The scalp incision is carried down to the cranium. A bone flap measuring approximately 4.5 cm. on each side is reflected forward, retaining its attachment to the skin. Four burr holes

FIG. 1. Disposition of the operative incision employed in the approach to the basal ganglia (Case 8 during the fourth postoperative week). Before being photographed, the incisional scar was touched up with ink.

FIG. 2. Reflection of the dural flap toward the midline. The cranial defect is of small size, representing a 4.5-5 cm. square.

FIG. 3. Site of cortical incision. This photograph was made after the lateral ventricle was entered. The effect of retraction and of drawing off cerebrospinal fluid was to make the incision gape and thus to appear wider than is the actual case.

are required for this flap. It is recommended that the two medial burr openings be made just lateral to the superior longitudinal sinus.*

The dura mater is incised just within the bony margin, and the dural flap is reflected toward the midline, avoiding damage to the pachionian granulations and the large cortical veins emptying into the superior longitudinal sinus (Fig. 2). The cortical incision through which the lateral ventricle is to be approached is planned so as to lie parallel to, and approximately 2 cm. from, the midline. In length it need not be greater than 3.5 cm. Its midpoint is crossed by an imaginary line estimated to represent the border separating area 6a β from area 8 (Fig. 3). Variations in the distribution of cortical vessels are encountered from case to case, and for this reason it may become necessary on occasion to modify the described incision so as to avoid the ligation of large arteries or veins.

* This precaution is intended to avoid the bleeding sometimes encountered when the thin shell of bone at the base of the burr hole is lifted away from the roof of the sinus. If the latter difficulty does arise or if bleeding from a pachionian body presents, electrocoagulation should be avoided, since it more often than not aggravates the hemorrhage. Hemostasis under these conditions is more readily accomplished by the use of a stamp of muscle, by traction sutures anchored over the bone, or by a combination of both measures.

The cortical incision is now carried into the brain,* always running parallel to the plane of the falx and just lateral to the deep folds of the cortex of the mesial aspect of the brain. By this means, troublesome bleeding from vessels lying deep in the sulci may be avoided. Shortly before the ventricle is reached, the direction of the white fibers may be seen to change. This change signifies that the upper surface of the anterior portion of the body of the corpus callosum has been reached. Gentle traction by means of narrow "S" retractors

FIG. 4 The head of the caudate nucleus (arrow) is exposed by "S" retractors.

provides an adequate exposure of the deep lying hemispherical structures.

The ventricle is entered and the available cerebrospinal fluid is drained by aspiration. The posterior half of the head of the caudate nucleus (Fig. 4) and the antermost portion of the tail of this structure as it sweeps over the anterior and superior mesial aspects of the thalamus are all clearly visible on the lateral wall of the ventricle. These structures should be protected from the blade of the "S" retractor by means of cotton patties. The foramen of Monro transmitting the choroid plexus is now readily identifiable, and a small cotton patty attached to a long silk thread is

* In my experience the tip of a bayonet forceps has proved the most useful instrument for carrying the incision through the substance of the brain. A fine metal suction tip may also be employed.

laid over the opening in order to prevent the seepage of blood (if any) into the third ventricle. The fornix constitutes the anterior rim of the foramen of Monro. By means of a No. 10 (pointed) Bard-Parker scalpel a short incision measuring 3 to 4 mm. in length is made across the inferior posterolateral face of this structure. The incision is just large enough to admit the tip of an instrument devised for sectioning the fibers of the ansa lenticularis (Fig. 5). This instrument is introduced through the incision and is carried

FIG. 5. Instruments employed for interruption of pallidofugal fibers. Above (a), the eyelet end of a soft probe is angulated so as to section the ansa lenticularis. The first angle is 45 degrees with reference to the axis of base. The second angle is 55 degrees with reference to the axis of base. Below (b), the metal applicator is bent so as to section the fasciculus lenticularis and the "fine fibers" of Papez.

downward and laterally, sliding along the superior-posterior edge of the anterior commissure and just below Crus I of the globus pallidus (Fig. 6). It has been demonstrated by Ranson and Ranson⁴⁴ that the fibers of the ansa lenticularis are derived almost exclusively from Crus I. The instrument is passed into the substance of the lateral wall of the ventricle until its second angle is within the ependymal lining, and from this position it is swept forward for a distance of approximately 6 mm. and backward for a distance of approximately 1 cm. The most medial and inferior fibers of the internal capsule will be avoided if the instrument is kept pressed home as described during the crucial maneuver. It is to be borne in mind throughout that the optic tract lies but a few millimeters behind

FIG. 6. Semidiagrammatic cross section of the basal ganglia at the level of the anterior commissure just rostral to the foramen of Munro. The broad line represents the horizontal plane of incision intended to interrupt the ansa lenticularis. Insert: A longitudinal schema of the pallidofugal fibers. The broad line represents the vertical plane of incision intended to interrupt the fasciculus lenticularis and the "fine fibers" of Papez. Abbreviations are as follows: A.C.—Anterior Commissure; A.L.—Ansa Lenticularis; E.C.—External Capsule; F.L.—Fasciculus Lenticularis; FN.—Fornix; I.C.—Internal Capsule; M.—Midbrain; PL.I.—Globus Pallidus, Crus I; PL.II.—Globus Pallidus, Crus II; PL.H.—Pallidohypothalamic Fibers; PUT.—Putamen; TH.—Thalamus; 3V.—Third Ventricle.

the posteromost limit of the section. The instrument is now withdrawn and a second instrument (Fig. 5) is introduced at the posteromost limit of the incision just described. This is swept vertically upward for a distance of 6 to 7 mm. It is intended by this maneuver to interrupt the "fine fibers" of Papez and the fasciculus lenticularis. In all probability the lower portion of Crus I of the globus pallidus is also damaged along the plane of this section.

The procedure described is practically bloodless. A small patty may be laid against the incision for a few minutes, as is practiced in chordotomy. When hemostasis has been accomplished, all patties are removed, the dura mater is resutured, and the bone flap is replaced and wired at two points. Closure of the fascia of the temporal muscle, galea, and skin is accomplished in separate layers with fine silk.

The postoperative measures required here differ in no wise from those appropriate to the care of other neurosurgical cases. Thus far, no postoperative physiologic disturbances have supervened in patients subjected to pallidofugal section which have not been encountered in the general run of cerebral sur-

gical procedures. Hyperthermia, blood pressure alterations, and hyperpnea have not presented serious problems in spite of the fact that the instrument employed for the section of the ansa lenticularis shears across the superior edge of the paraventricular nucleus.

The designation of this procedure as "interruption of the pallidofugal fibers" is obviously insufficient, since several other neural structures are incidentally damaged—notably, the cortex of areas 6 and 8 along the line of the incision and certain subcortical, corpus callosal, fornical, thalamofrontal, pallidohypothalamic, pallidothalamic, pallidohabenular, and (possibly) anterior commissural fibers. The term employed is therefore permissible only if it is implicitly understood (as in the use of terms such as section of the lateral spinothalamic tract, section of the lateral pyramidal tract, tractotomy of the descending spinal tract of the trigeminal nucleus, etc.) that other neural elements than those upon which attention is focused are also implicated.

Summary

Although a wide variety of pharmacologic, biologic, dietary, physical therapeutic, and psychologic agents has been employed, the treatment of parkinsonism still remains generally unsatisfactory. Within the past decade efforts have been made in several clinics to devise a surgical procedure on the central nervous system which might benefit one or more of the major features of this syndrome. The "central" operations that have been tried include section of the anterolateral, dorsal, and lateral pyramidal tracts of the spinal cord; ablation of portions of the motor and premotor cortex; extirpation of the dentate nucleus of the cerebellomesencephalic complex; and several procedures on the basal ganglions.

Because knowledge concerning the physiologic, pathologic, and pathogenic considerations relating to paralysis agitans is as yet in a highly uncertain state, it has been difficult to formulate a self-sustaining rationale for the several surgical procedures attempted. Unfortunately, the syndrome is not encountered in veterinary medicine, and thus far it has not been possible to reproduce the picture in laboratory animals. The present era is therefore one of empiric experimental surgery, and the subjects of experimentation are of necessity patients suffering from the syndrome.

The protocols of my present series of cases

subjected to operations on the basal ganglions have been published in detail elsewhere.^{1,2-4} Among 9 cases, the most effective measure (employed in Cases 7, 8, and 9) appears to be interruption of the pallidofugal fibers. Following this operation, alternating tremors are promptly and effectually improved, and rigidity, together with its secondary symptomatic effects such as akinesia, bradykinesia, deficiency of automatic associated movements, etc., is much diminished. The operation involves no enduring disturbance of sensory, motor, reflex, coordinative, language, euphraxia, intellectual, vegetative, or hormonal functions. It is seemingly capable of being applied to bilateral, as well as unilateral, cases of paralysis agitans, and it is conceivable that by breaking across the septum pellucidum (as in Case 7) a bilateral procedure carried out in a one-stage operation may come to be routinely employed.

The principles that guide the selection of the patient for surgery have been outlined. In brief, they call for a subject in whom the nature of the disease process is, at least from the clinical standpoint, clearly identifiable as parkinsonism and who in spite of a well-supervised medical regimen has proved refractory to the standard conservative therapeutic measures. The patient should be reasonably intelligent and cooperative and should represent a good operative risk.

The clinical and laboratory work-up of the surgical patient should be concerned with establishing the base lines of his general and special somatic, vegetative, hormonal, and psychologic processes so that the effects of operation may be accurately judged.

The technic of surgical interruption of the pallidofugal fibers is described. In substance, the operation calls for a short cortical incision through the premotor area, close to the midline and parallel to the plane of the falx. This incision is carried into the lateral ventricle, and from here the pallidofugal fibers are sectioned by means of two special instruments introduced at the anterior rim of the foramen of Monro.

From the technical standpoint the procedure described is relatively simple and susceptible of standardization.

THOUGHTFUL

A while ago the Academy of Medicine offered a lecture by an English psychiatrist on the subject of war neuroses. This attracted an overflow crowd, and so a loudspeaker was placed in a second lecture room, on a table. A lady who was a member of the loudspeaker audience

reports that just before the talk began an attendant came in with a pitcher of water and a glass. He placed these beside the amplifier and retired, looking pleased with himself.

ALUMNI DAY—NEW YORK UNIVERSITY COLLEGE OF MEDICINE

The date of the Annual Alumni Day at New York University College of Medicine has been changed back to the usual Washington's Birthday dates of February 20 and 21, 1942.

The program will begin with a dinner for all

the alumni and their wives at the Hotel Essex on Friday, February 20. On Saturday, February 21, there will be a scientific session at the medical school during the morning and afternoon and a luncheon in the lounge at noon.

THE VALUE OF HELIUM IN THE PREVENTION OF EXPLOSIONS OF ANESTHETIC MIXTURES

Experimental Data

GEORGE J. THOMAS, M.D., and GEORGE W. JONES, Pittsburgh

THIS is one of a series of publications issued as a result of a cooperative investigation between the Bureau of Mines, U. S. Department of the Interior, the St. Francis Hospital, Pittsburgh, and the University of Pittsburgh, relative to the explosion hazards of combustible anesthetic mixtures. Methods of eliminating such hazards through the addition of sufficient inert gaseous material such as helium or nitrogen have been proposed. The experimental results given in this report concern the elimination of explosion hazards of cyclopropane-oxygen, ether-oxygen, and ethylene-oxygen mixtures through reduction and control of the oxygen content by replacement of part of the oxygen by helium.

The method is based on the fact that every combustible gas, vapor, or dust will not burn or explode when the oxygen content of the mixture is reduced below certain definite proportions. These critical oxygen percentages are usually different for each combustible and vary with the inert gaseous material used to reduce the oxygen content of the mixtures and with the percentage of combustible present in the mixtures.

In the case of combustible anesthetics such as cyclopropane, ether, or ethylene, the concentrations of these cannot be altered extensively because definite amounts are required to give the desired degree of anesthesia. Nonexplosibility must, therefore, be brought about by replacing part of the oxygen with some inert, nontoxic gaseous medium that possesses the desired flame-quenching characteristics and be least objectionable to the patient breathing the mixture.

As shown in a previous Bureau publication,¹ those imposed limitations confine the inert gaseous mediums that may be used largely to helium and nitrogen. The value of nitrogen in the prevention of explosions has

been reported recently by Haas, Hibshman, and Romberger.²

Helium has certain desirable characteristics not possessed by nitrogen, both from the standpoint of the patient and the ability of helium to aid in the prevention and dissipation of static ignition.

Helium is one of the family of so-called inert gases which possesses the remarkable properties of extreme chemical inactivity and complete resistance to ordinary chemical changes. It is colorless, odorless, tasteless, and one of the lightest gases known, being about one-seventh the density of air. As recent as 1915, helium was merely a laboratory curiosity obtainable only in small quantities at the tremendous cost of about \$2,500 per cubic foot. Owing to its discovery in appreciable amounts in certain natural gases in the United States and the subsequent development of cheap and efficient methods of recovery, it is now being produced by the U. S. Bureau of Mines at a cost of less than 2 cents per cubic foot. Because of its present low cost and availability in large quantities for medicinal use, it became decidedly attractive as an agent for the prevention of explosions in the operating room for the following reasons: (1) Because of its low density, mixtures containing high concentrations of helium are much easier to breathe by the patient. (2) Because of its almost perfect inertness and low solubility in water and body fluids, it should exert no physiologic effect on the patient breathing it, provided normal proportions of oxygen are maintained. (3) Because of its property of high conducting power for heat and electricity, it has a decided advantage in the prevention of static ignitions of explosive anesthetic mixtures.

Barach,³ Eversole,⁴ Bonham,⁵ Sykes,⁶ and others have used helium for various reasons. As to whether any of these investigators have used sufficient proportions of helium to render the mixtures nonexplosive cannot be definitely stated.

The present paper deals with experimental work, giving the proportions of helium which must be present to maintain the mixtures outside the explosive range and, therefore, in-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941. Published by permission of the Director, Bureau of Mines, United States Department of the Interior.

Instructor of anesthesia, University of Pittsburgh, School of Medicine, and director of anesthesia, St. Francis Hospital, Pittsburgh; and chemist, Explosives Division, Central Experiment Station, Bureau of Mines, Pittsburgh, respectively.

capable of propagating flame irrespective of the source of ignition. It is not the purpose of this report to give in detail the exact procedure by which the inflammable and explosive ranges for the different combustible anesthetics—cyclopropane, ether, and ethylene—were obtained nor the various factors that affect the limits. Briefly, apparatus and procedures were employed which gave the widest range of inflammability, so that any mixtures that would fail to propagate flame in the equipment employed likewise would fail to propagate in anesthetic equipment, irrespective of the source of ignition, direction of flame propagation, or shape of the equipment.

Cyclopropane-Oxygen-Helium Mixtures

The explosibility of cyclopropane-oxygen-helium mixtures has been discussed in a previous report.¹ However, in order to compare the explosive and nonexplosive areas of cyclopropane with those for ether and ethylene, the curves are reproduced in this report. The limits of inflammability of all possible mixtures of cyclopropane-oxygen-helium mixtures are given in Fig. 1. It will be seen that diluting cyclopropane-oxygen mixtures with helium has only a minor effect on the lower limit of inflammability. The results indicate a slight decrease from 2.48 per cent for the lower limit of cyclopropane in pure oxygen to 2.15 per cent when the atmosphere contains about 75 per cent helium. The upper limit is seen to be affected markedly by the amount of helium present as shown.

From the curves given in Fig. 1 it becomes apparent that anesthetic mixtures below the lower limit of inflammability cannot be used, since such mixtures to be noninflammable must contain less than about 2.15 per cent of cyclopropane and are, therefore, too dilute for general anesthesia. However, a whole series of mixtures may be used that are above the upper limit of inflammability and, therefore, are noninflammable until air or oxygen is added to the mixture. All mixtures falling in the area to the right of curve *CE* and containing 3 to 60 per cent of cyclopropane may be used safely.

If it is desired to control the atmosphere in the anesthetic machine so that the composition at all times is outside the explosive area, the comparative explosive hazards can be obtained from the graph, provided the composition of the mixture is known. If a mixture represented by the point *J* (25 per cent cyclopropane, 25 per cent oxygen, and 50 per cent helium) is decided upon, the following

FIG. 1. Inflammability of cyclopropane-oxygen-helium mixtures.

method of administration may be followed. In a closed, recirculating, anesthetic apparatus the free space in the machine and the patient's lungs when administration is begun will consist largely of normal air containing approximately 20.9 per cent oxygen and no cyclopropane. This condition is represented by point *H*. As the 25, 25, and 50 per cent cyclopropane-oxygen-helium mixture is administered, the composition of the mixture in the apparatus and patient's lungs will shift along the broken line from *H* to *J* and pass through a narrow range of explosive mixtures as shown. However, this phase can be carried out without appreciable explosive hazards, since recent tests have shown that when the mixtures contain about 70 per cent of helium normal induction coil or static sparks are unable to ignite such mixtures containing less than about 19 per cent of oxygen, as shown in Fig. 2. They will, however, propagate flame rather rapidly if flame ignition is resorted to as shown in Fig. 1.

The mixture represented by *J* can then be administered to the patient throughout the anesthesia without danger of explosions inside the machine. (Additional oxygen must be administered to replace that demand by the basal requirement of the patient.) Should leakage occur about the mask or other parts of the machine, "flashes" may occur at the point of leakage if the gas becomes ignited,

FIG. 2. Inflammability of cyclopropane-oxygen-helium mixtures. Effect of type ignition.

because the addition of air to the mixture, represented by *J*, will shift the composition of the mixture to the left along line *JH* and the mixture will become explosive in the area shown.

At the end of the period of anesthesia, when the mask is removed and the patient is allowed to breathe normal air, the mixture in the patient's lungs also will traverse this same line from right to left and an explosive mixture will be present for a short period.

To use cyclopropane-oxygen-helium mixtures in nonexplosive proportions, in which the mixtures are above the upper limit of inflammability, makes it mandatory that the patient's lungs contain explosive atmospheres for a short period both at the beginning and at the end of the administration of the anesthetic but obviates the necessity of employing highly explosive mixtures throughout the anesthetic processes, as is the general practice. Even these short periods at the start and end of the administration can be, and are being, eliminated in our recent clinical experiments by increasing the amount of helium present at the start of the administration and purging the patient's lungs at the end of the administration with helium-oxygen atmospheres containing reduced percentages of oxygen.

It can be reported that the method of prevention of explosive atmospheres of cyclopropane in anesthetic apparatus, through the control of the oxygen content by the use of helium, is now being carried out in three different hospitals in the Pittsburgh district and comprises hundreds of clinical experiments made during the last twelve months.

Ether-Oxygen-Helium Mixtures

Some interest has been shown in the use of ether-oxygen mixtures, since ether is used alone with oxygen or air and, in some instances, in conjunction with cyclopropane.

Laboratory investigations using the same type of explosion apparatus and similar experimental conditions were made to determine the explosive area of all possible mixtures of these gases. The results are given

FIG. 3. Inflammability of ethyl ether-oxygen-helium mixtures.

in Fig. 3. Ether presents the peculiar properties of exhibiting so-called "cool flame" characteristics when the concentrations of ether in the oxygen exceeds certain percentages. To outline roughly this area of "cool flame," a separation has been made, and the area has been designated "aldehydic combustion" because of the fact that copious quantities of aldehydes were formed during the propagation of the pale blue to almost invisible flames through these mixtures. Otherwise, the method of presenting the results are the same as that given for cyclopropane in Fig. 1.

It will be seen that the oxygen requirements to prevent inflammable conditions are much lower in the case of ether than of cyclopropane. In fact, the mixtures must not have oxygen present in amounts greater than about 15 per cent if inflammability of the mixtures is to be prevented.

Whether helium can be added to ether-oxygen mixtures in sufficient proportions to

obtain noninflammability and still have sufficient oxygen present to meet the patient's requirements is not at all certain. The addition of helium to the point where the mixtures are brought into the area of aldehydic combustion would greatly reduce the explosive violence of the mixtures, but whether it would prevent flame propagation when ignited by induction coil or static sparks requires further experimental work.

FIG. 4. Inflammability of ethylene-oxygen-helium mixtures.

Ethylene-Oxygen-Helium Mixtures

Tests similar to those described under cyclopropane and ether were conducted with ethylene-oxygen-helium mixtures, and the results are given in Fig. 4.

The results show that noninflammability of ethylene-oxygen mixtures can be obtained by the addition of helium without reducing the oxygen content to the extent of that found for ether. For mixtures containing from 20 to 80 per cent of ethylene the oxygen requirements to prevent inflammable mixtures are rather constant and range between 15 and 20 per cent.

Comparative results showing the oxygen requirements to prevent inflammability of cyclopropane, ether, and ethylene-oxygen mixtures when helium is used to replace part of the oxygen are shown to better advantage in Fig. 5.

As far as the lower limits of inflammability

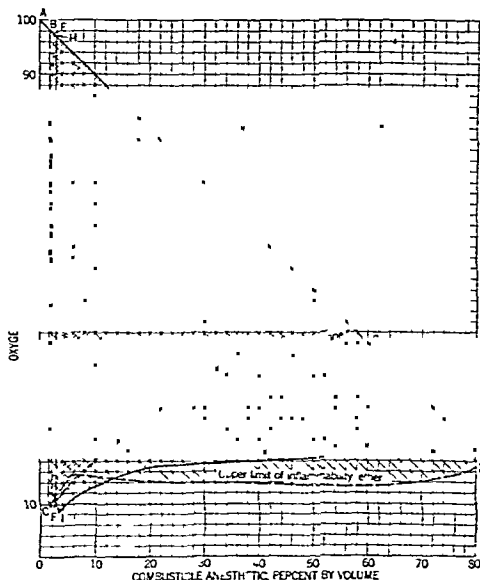

FIG. 5. Inflammability of cyclopropane-oxygen-helium, ethylene-oxygen-helium, and ether-oxygen-helium mixtures.

are concerned, they all lie so close together that there is little to choose between the different anesthetics.

In the case of upper limit mixtures (the ranges in which the anesthetics must be used), it is seen that there is marked advantage as far as oxygen requirements are concerned in the addition of helium to cyclopropane-oxygen mixtures for the prevention of explosions. For example, taking 20 per cent mixtures of each anesthetic, we find that the oxygen content in the case of ether should not exceed 14 per cent; ethylene, 17 per cent; cyclopropane, 26 per cent.

Taking equal percentages of each combustible anesthetic is not a fair comparison because the potency of the different anesthetics is not the same. Still, even when this factor is taken into consideration, it can be seen that the use of cyclopropane-oxygen-helium mixtures alone, without the addition of either ether or ethylene, offers the greatest promise in obtaining noninflammable mixtures because it is not necessary to reduce the oxygen content to the point where such diminution might become intolerable to the patient.

Technic for Administration of Noninflammable Cyclopropane-Oxygen-Helium Mixtures

The following technic has been devised for the administration of noninflammable cyclo-

Note.—Induction smooth. Relaxation satisfactory. Color good. Anesthesia satisfactory.

propane-oxygen-helium mixtures. The technic recommended is for the average adult patient. The dosage must be governed by the patient's metabolic requirements and by the type and degree of premedication. Furthermore, we have found it necessary to vary our technic when using different types of apparatus because the calibration of gas machines vary. However, this last procedure may soon be corrected by the manufacturers. Therefore, in using cyclopropane-oxygen-helium mixtures, a close observation must be kept of the patient and a proper adjustment of the various gases must be made in order to maintain the desired plane of anesthesia.

The gas machine must be equipped with a carbon-dioxide absorber and a helium attachment having calibrated flowmeters covering a range from 100 to 5,000 cc. per minute. There also must be a 5- to 7-L. gas bag.

Adequate and proper premedication is essential for satisfactory anesthesia.

1. Purge the gas machine for two minutes with 500 cc. of oxygen and 3 L. of helium in order to eliminate any residual gas from a previous anesthetic.

2. Empty the bag.

3. Set the needle valves so the gases will flow in the following proportions: oxygen, 500 cc. per minute; cyclopropane, 500 cc. per minute; and helium, 1,000 cc. per minute.

4. Place the mask securely on the patient's face. Administer the above proportion for three minutes then change to the following: oxygen, 500 cc. per minute; cyclo-

propane, 500 cc. per minute; and helium, 150 cc. per minute.

5. Continue the above mixture until the patient enters the desired plane of anesthesia. Then administer the oxygen according to the patient's metabolic requirements. This usually requires from 250 to 450 cc. per minute. Use only sufficient oxygen to satisfy basal requirement.

The cyclopropane is administered *continuously* at rates varying from 50 to 200 cc. depending upon the plane of anesthesia desired.

If the bag becomes too greatly distended reduce the helium to 100 cc. It may, however, be necessary to release the pressure at frequent intervals at the exhaling valve.

Note.—The carbon-dioxide filter should be turned on at the beginning of the administration of the anesthetic or shortly thereafter because of the accumulation of carbon dioxide that usually occurs during anesthesia. If there are any signs of cyanosis or changes in the rhythm of the pulse, oxygen should be increased to correct these conditions.

At the completion of the anesthetic all the gases should be turned off, the face mask removed, and the machine pushed away from the patient.

We do not believe in flushing the patient with oxygen after the termination of the anesthetic. This is extremely dangerous because it will immediately throw the mixture into the explosive range. However, if one should feel it absolutely necessary to flush the patient, we recommended the use of one part of oxygen with five parts of helium.

In the event of leakage about the face mask or any other part of the anesthetic apparatus, the bag may be refilled by using the technic described in the induction period.

A typical example of the above technic is illustrated by Case 73 given in Table 1.

Conclusions

The method presented in this report for the prevention of explosions of combustible anesthetic mixtures is that of controlling the oxygen concentration of the mixtures within such limits that the mixtures are outside the explosive range.

The method is based on the fact that every combustible gas, vapor, or dust will not burn or explode when the oxygen content of the mixture is reduced below certain definite values. These critical oxygen values are usually different for each combustible and vary with the inert gaseous material used to reduce the oxygen content of the mixture

and with the percentage of combustible present in the mixture.

In the case of combustible anesthetics such as cyclopropane, ether, and ethylene, the concentration of these cannot be altered to any great extent because definite amounts are required to give the desired degree of anesthesia. Nonexplosibility must therefore be brought about by replacing part of the oxygen with some inert, nontoxic gaseous medium that possesses the desired flame-quenching characteristics and is least objectionable to the patient breathing the mixture.

This report gives additional information relative to the explosibility of cyclopropane-oxygen-helium, ether-oxygen-helium, and ethylene-oxygen-helium mixtures.

The results show that ether requires the lowest range of oxygen concentrations to maintain the mixtures outside the explosive range, that ethylene occupies an intermediate position between ether and cyclopropane, and

that cyclopropane (in concentrations in the upper limit range) permits a higher concentration of oxygen to be present while maintaining nonexplosive conditions.

On the basis of the laboratory results it is indicated that helium can be used to the best advantage in cyclopropane-oxygen mixtures for the prevention of explosions and to a slight advantage in the case of ethylene or ether-oxygen mixtures.

A technic and illustration were also submitted showing the administration of nonexplosive cyclopropane-oxygen-helium mixtures.

Workmen's Compensation

The Medical and Claims Departments of the various insurance carriers were notified by the Compensation Insurance Rating Board on July 14, 1938, of a plan of procedure relating to the discontinuance of medical treatment then proposed by the Labor Department. This procedure was subsequently modified upon recommendation of the Labor Department. These modified rules and regulations were adopted by the Industrial Council and promulgated by the Industrial Commissioner on January 8, 1940. They were sent out to the various insurance carriers by their organization on July 17, 1940. We are reprinting these rules below and are requesting physicians to advise us at once if insurance carriers or self-insurers are not complying with them.

It is obligatory for an employer or insurance carrier before requesting a physician to stop treatment to have an examination of the compensation claimant made by a qualified medical examiner. A copy of the medical report must be sent to the attending physician. Recently, the insurance carriers organization has again instructed their Claims Department to carry out this procedure. Physicians who have received requests to stop treatment without the necessary report of the medical examiner should communicate the fact to this office at once, giving full details.—David J. Kaliski, M.D., Director, January 19, 1942

Procedure for Adjusting Differences of Opinion Between Attending Physicians and the Examining Physicians Employed by Carriers and Employers as to the Need for Further Treatment

Rule 1.—The employers or insurance carriers must exercise their right to have a medical examination made of a compensation claimant by their medical examiner, on which a direction to the attending physician to stop treatment must be based.

Rule 2.—A request forwarded to the attending physician to stop treatment must be accompanied by a report of the medical examiner employed by the employer or insurance carrier setting forth the physical findings.

Rule 3.—If the attending physician does not agree with the findings of the medical examiner, he must arrange to confer with the medical examiner for the purpose of reaching an understanding.

Rule 4.—If the attending physician and the medical examiner are unable to agree, a joint examination of the claimant should be arranged for the purpose of comparing the findings of both the attending physician and the medical examiner.

"Rule 4 is not mandatory although the Representatives of the carriers and employers agreed that this procedure should be used whenever possible."

THE RESULTS OF TREATMENT WITH BACILLUS COLI METABOLIN IN ALLERGIC RHINITIS

HARRY H. SHILKRET, M.D., New York City

IN THE June 15, 1941, issue of the NEW YORK STATE JOURNAL OF MEDICINE, Elsbach¹ reports 75 cases of allergic rhinitis treated with a preparation called "Coli Metabolin." He speaks of it as a "new biologic treatment . . . which appears to act to a high degree as a stimulant to the natural functions of the sympathetic system and renders it foolproof so that it no longer reacts to any irritant . . . and seems to have a desensitizing effect on it." This product is obtained by culturing the *Bacillus coli* found in the human intestines on "specific" culture mediums, incubating the pure cultures at body temperature, transplanting them, attenuating them, and then diluting them with physiologic salt solution. After septic filtration the metabolins in the clear liquid are used therapeutically.

His treatments consisted of eight to twelve intramuscular injections of 2 cc. each of the *B. coli* Metabolin; the first five injections were administered within five days and the remainder were given at intervals of one to two days. Treatments were begun at the onset of acute symptoms. No protocols or bibliographic materials were included in this report, nor was it stated at what period of time the experiments were carried on.

In his series a study was made of 75 cases of allergic rhinitis. These were divided into two groups: those presenting seasonal symptoms and those with perennial symptoms. No skin tests were made. Of the 75 cases under treatment with *B. coli* Metabolin, he claims a cure in 53 cases (70.7 per cent); improvement in 21 cases (20 per cent), and a poor result in 1 case (1.3 per cent). The author does not interpret the term "cured."

In a personal communication with the author, he informed me that this work was done in 1940. He mentioned that some of this work had been done in Germany with some success.

Soon after Elsbach's results appeared in the NEW YORK STATE JOURNAL OF MEDICINE, statements of a "cure" for hay fever and other allergic conditions also appeared in several

newspapers quoting his article. Physicians throughout the United States asked for supplies of *B. coli* Metabolin, and many have already used this preparation in the treatment of all types of allergic cases. The reports and the results of a considerable number of these cases are now in the possession of the Tosse Laboratories.

Many patients attending our clinics with allergic conditions have made requests for this "cure" treatment. Because of this and because of the excellent results reported by Elsbach, we were prompted to investigate the value of *B. coli* Metabolin.

In our series 20 cases were studied. Ten of these suffered with ragweed sensitivity; the remaining 10 had perennial allergic coryza.

Of the hay-fever patients, 5 were uncomplicated types, 3 had slight asthmatic symptoms, and 2 had histories of symptoms after the hay-fever seasons.

Of the patients with perennial allergic coryza, 8 were uncomplicated cases, 1 had occasional attacks of mild asthma, and another had polyps of the nose.

Following the treatment outlined by Elsbach, at least ten injections, at intervals as nearly as possible as those suggested by him, were given each of the patients we studied. Treatments were given only to those who presented acute rhinitic symptoms.

The groups of patients with hay fever were studied at the City Hospital Allergy Clinic; those with perennial allergic coryza, at the French Hospital. The treatments were begun in our hay-fever group on August 26, 1941, when the supply of *B. coli* Metabolin was first available to us. The patients with perennial symptoms started their therapy on October 15, 1941, after the ragweed season. Each group was purposely treated during the same period of time.

In all cases careful histories were taken, progress notes were recorded, and daily symptom charts were kept. In the hay-fever group, notes were kept from August 12, 1941, to October 1, 1941. In our second group (with perennial allergic coryza), records were kept from August 1, 1941, to November 1, 1941. Intradermal tests consisting of the most important inhalants and ingestants were performed on all the patients. Nose and throat

10	C	Asthma	10	Seasonal—good	10	0	Poor

consultations were made on the cases of allergic rhinitis, and the reports are included in our charts. To serve as a comparison, notes were made of the previous treatments received by our patients, and their opinions as to the results they obtained were recorded. Particular attention was noted of their treatments during 1940.

To correlate our results with patients who were treated with the accepted forms of pollen therapy, we referred to our daily records of symptoms and progress notes which were kept of many other patients with hay fever under perennial and preseasonal therapy. In order to make our results comparable, we chose 10 cases each of hay-fever patients treated perennially and preseasonally, respectively, during 1940 and 1941 and computed the results obtained from these forms of therapy. The charts of these patients were chosen in alphabetical order, and only those charts were accepted which had the necessary progress notes and in which the patients' records showed completed treatments.

In calculating our final results, we used the same standards in all cases—that is, we recorded the number of days in which the patients had moderate to severe hay-fever symptoms, from August 12 to October 1, 1941. Subtracting these days from the fifty "ragweed fever days" gave us the number of symptom-free days. Then the percentage of relief was obtained by dividing the number of symptom-free days by fifty. We finally expressed our results by using the following standards: 90 to 100 per cent, considered excellent results; 80 to 90 per cent, considered good results; 70 to 80 per cent, considered fair results; and 65 per cent or less, considered poor results.

In the cases with perennial coryzas, we depended upon the patients' impressions as to the results they had with their former treatments as compared with B. coli Metabolin.

After our results on B. coli Metabolin were computed and the progress notes were studied, Durham's survey of the pollen counts of the ragweed seasons of 1940 and 1941 were referred to.

Results

1 (Table 1). Of the 10 cases with hay fever treated with B. coli Metabolin, 8 were relieved of their symptoms for only three to ten days out of the fifty days they were under our observation. In other words, most of them suffered at least forty to forty-seven days during the ragweed season; the remaining 2 suffered during the entire fifty days. In this group the most common of the symptom-free days occurred on certain days and did not seem to be related to the number of injections given to a patient. They occurred on August 12 to 14 and 18 to 20, before the injections were given, and on August 27 to 29, September 2 to 4, 12 to 13, and 29 to 30, after the injections were begun. After the treatments on these 10 patients were completed, all of them felt that they had little or no relief from this form of therapy. One patient with asthma required hospitalization. After receiving their injections, 2 complained of stomach cramps, 1 complained of diarrhea, and another complained of headaches. A few patients did not return for further treatments and are not included in this study. Those patients who had previously been treated with the accepted forms of therapy felt that they did much better with their former treatments.

2 (Table 2). Of the 10 cases with allergic coryza treated with B. coli Metabolin, 6 of them were relieved of their symptoms from one to four days, and the remaining 4 had no relief during the thirty days after their injections were begun. In other words, most of them suffered twenty-six to thirty days of the thirty days they were observed. On questioning them, they said they felt that their

Number of days observed	50	50		50
Average percentage relief	88%	80%		12%
Interpretation	Good	Fair		Poor
Results 1940: perennial, excellent; coseasonal, good		excellent; preseasonal, ex-		

new therapy gave them much less relief than the therapy they previously had, even though they had had only fair to good results from them. Three of this group felt that B. coli Metabolin made them feel worse, and 2 refused to continue further with these treatments. After her third injection, one of this group developed angioneurotic edema and asthma for the first time since the onset of her illness two years before.

Comment

Assuming that by "cure" Elsbach means a cure of symptoms rather than a cure of the disease, the results he obtained in 1940 are only fair. This is significant since the general experience among allergists shows that the year 1940 was one of clinically mild hay fever. The results obtained in our clinics is outlined in Table 3. During that year most of our patients had excellent results with both perennial and preseasonal therapy and even good results with coseasonal therapy. The general experience in 1941 has been of severe hay-fever symptoms with results of therapy, in any form, not so favorable as those of 1940. In 1941 we had our best results with perennial therapy and only good results with preseasonal therapy. If you will compare (Fig. 1) the survey of pollen counts as published by Durham² in 1940 and 1941, you will see the direct reason for the severe hay-fever season in 1941 as compared with the mild one in 1940. Perhaps this is the reason for Elsbach's favorable report.

It is also interesting to note that with B. coli Metabolin the most common symptom-free days in our group of 10 patients during the 1941 ragweed season, occurred on the following dates: August 10 to 14, 18 to 20, 27 to 29; September 2 to 4, 12 to 13, 29 to 30. The symptom-free days, therefore, apparently coincided with the definite drops in the pollen

FIG. 1.

count, as is shown in Fig. 1. Since none of these patients had relief on the higher pollen count days, we can say that the alleviation of symptoms in our series of cases was due to favorable meteorologic conditions rather than to the efficacy of the medication.

In our series of perennial allergic coryzas where there is no specific measure of antigenic content of the environment and where the antigenic index, for the most part, remains fairly stable, we had to depend entirely on the subjective reaction of the patient as to results with the new therapy and the comparison of these with the results from the orthodox therapy of specific hyposensitization. Here, in our experience, the orthodox therapy gives only fair to good results. In spite of this, the patients themselves preferred this accepted form of therapy to that with B. coli Meta-

bolin. In this group, three patients refused to continue with B. coli Metabolin because they felt it made them worse. One of these patients who suffered from perennial allergic coryza for two years developed angioneurotic edema and asthma for the first time after receiving the third injection. Whether or not this was a constitutional reaction to the medication, we are not prepared to say. We intend, shortly, to study this phase of the problem.

Conclusion

B. coli Metabolin is of no value in the treatments of hay fever or allergic coryzas.

IMPROVING ADVERTISING STANDARDS

The Pennsylvania Newspaper Publishers Association is playing an important role in that state toward improving standards of advertising. The committee has suggested twelve guides specifically connected with the advertising of proprietary medicines, several of which, if adopted, says the *Pennsylvania Medical Journal*, will undoubtedly prove effective in curing the duping of newspaper readers who are inclined to swallow any claim for any remedy for any condition that they, through the processes of self-diagnosis, believe is their own particular ailment. They are:

The display lines of medical advertisements should not duplicate, or too closely resemble, regular news dress.

The following advertising should be carefully scrutinized with the possibility of elimination, since copy of this nature in a large percentage of cases is fraudulent: Bright's disease, cancer cure-alls, deafness (except mechanical devices), diabetes, diphtheria, dropsy, epilepsy, gallstones, goiter, heart disease, high blood pressure, infantile paralysis, leg sores, obesity, prostate gland, remedies given secretly, stomach ulcers, tuberculosis, venereal diseases.

Advertisers cannot claim that a product will cure: this applies either by direct statement or by various forms of inference. The words "rid," "check progress," and "remove the cause" fall in this category.

Any advertising regarding internal ailments which offers to "diagnose, prescribe, or give special instructions for treatments of particular cases by mail" should not be published.

Implied or direct reference to the restoration of "lost manhood or womanhood, full vigor of manhood or womanhood," etc., should be barred.

All remedies taken internally, or applied externally, which claim to reduce weight should be eliminated.

No reference should be made to the fact that "your doctor would recommend" a specific product. "Doctors everywhere" falls under this same provision. Names of specific doctors may be used.

WHAT'S YOUR E. Q.?

[E. Q. = Emotional Quotient, in case you are wondering.]

An emotionally mature person, says Helen R. Sherman, instructor in the Adult Education Division, Wayne University, has some idea of what he wants to get out of life. He can take responsibility and make decisions. He can accept blame, criticism, and praise casually. He can suffer without disintegration; i.e., he has courage. He is ready to put himself to the test. He realizes effort rather than luck is the foundation of success.

An emotionally mature person has an objective, fairly accurate idea of himself. He knows his strong points and his weak ones and is aware of his biases, prejudices, and fears. He is fair, not conceited, not sorry for himself, has a sense of humor. He does not habitually ask that favors be done him. He can plan his time and is seldom late or rushed.

An emotionally mature person habitually faces the situation as it is and not as he wishes it were. He adjusts to unchangeable facts with the least possible discomfort. He lives in the present, does not rehearse the failures or hurts of the past, plans for but does not worry about the future.

An emotionally mature person does not expect perfection from himself or others and does not fret over minor personality defects. He knows that there must always be error and conflict and that there is no easy, quick solution for difficult problems. He knows that improvement of behavior in self or in others requires time, skill, wisdom, and self-sacrifice. He puts his attention on the successful aspects of his own and other people's lives. He has confidence, tolerance, and zest.—*Talk, published by The National Hospital for Speech Disorders*

CHRONIC HYPERTROPHIC OSTEOARTHRITIS IN THE CERVICAL SPINE WITH RADICULITIS

A Report of 40 Cases with a Review of the Literature Together with Some Notes on Effective Methods of Treatment—Part III

LE MOYNE COPELAND KELLY, M.D., F.A.C.P., New York City

Differential Diagnosis

When a patient presents himself for the relief of pain in the neck, shoulder, or upper extremity, there are a great variety of conditions which must be considered: (1) *local conditions* in the shoulder, breast, or chest wall—for example, an arthritis of the shoulder joint, subdeltoid or subacromial bursitis, muscle sprain, tumor of the breast, or fractured rib; (2) *lesions in the spinal column*, the spinal cord or its roots—viz., cervical rib, tumors, intercostal neuralgia, and various neuritides (toxic, infectious, or that associated with avitaminosis); (3) *shoulder pains referred from visceral diseases* as seen in gastrointestinal disorders (notably of the stomach and gallbladder) and pulmonary lesions such as pleurisy and Pancoast's superior sulcus tumor; and (4) *metabolic disorders* (particularly hypothyroidism). A good idea of the difficulties that may arise in making the diagnosis in a patient complaining of painful shoulder may be obtained from Case 17.

Case Report

Case 17.—Mrs. E. H., aged 58, was seen in a dispensary in September, 1940, complaining of "arthritis" in the left shoulder for a period of twelve years and acute pain in that shoulder on the slightest motion for the previous two weeks, together with "pains all over" for three months and knifelike abdominal pain "off and on for six weeks." On physical examination the patient complained bitterly of excruciating pain in the left shoulder when it was moved in any direction, but more so on abduction, and there was marked tenderness on direct pressure over the insertion of the deltoid muscle. Her throat was injected and pus could be expressed from the tonsils. The clinical impression was that she had an acute subdeltoid bursitis with possibly some osteoarthritic change in the left shoulder joint.

An x-ray of that shoulder showed peritendinous calcification and the sedimentation rate was considerably elevated, all of which tended to bear out our diagnosis. However, when five physical therapeutic treatments failed to produce any benefit, she was sent to the roentgenologist for deep x-ray therapy. His summary, which describes so well the usual history in these cases, was as follows: "For the past seven years this

patient has been treated for various types of pain which seems to have involved most of her body at one time or another." He advised deep x-ray therapy to the left shoulder and the patient received this (1,600 r units in air) within a period of eighteen days. At the end of this time, however, she was not improved and the same marked limitation of motion was still present.

About a month later she returned complaining of pain in the region of her left trapezius muscle with radiation down over the deltoid and lateral aspect of the left arm as far as the wrist. This was always worse just before bad weather and she described it as being so severe at times that she "could not even raise her hand to comb her hair." There was also some occipital headache in the morning upon awakening. X-rays of the cervical and dorsal spine at this time showed a narrowing of the intervertebral space C 1-2 (particularly on the left side), together with other changes characteristic of hypertrophic osteoarthritis. There was considerable bony bridging in the lower dorsal area. Therefore, x-ray therapy was given, this time to the cervical spine, and after 1,200 r units in air her symptoms had largely disappeared.

Special note: Two weeks after first being seen for the shoulder pain, this patient returned to the clinic complaining of sharp pains in the epigastrium not related to food or activity. These radiated up behind the sternum and were followed by a bilateral soreness beneath the lower ribs (her gallbladder had been removed fifteen years previously). A gastroenterologist who saw her during one of these episodes of pain said: "The patient's symptoms may be cardiac, but I think we should rule out the gastrointestinal tract." Gastric analysis was normal and a gastrointestinal series showed only a small diverticulum of the second portion of the duodenum. Examination of her abdomen at the time of the shoulder pain had revealed considerable tenderness in both lower quadrants, and there was still some slight tenderness in the epigastrium and both lower quadrants when examined for her epigastric pain two weeks later. However, when seen again, six weeks after the original gastric episode, all the abdominal pain and tenderness had entirely disappeared.

Just as symptoms of a radicular nature from an arthritis of the cervical spine should call our attention to the possibility of associated gastrointestinal symptoms being on a

radicular basis, so should symptoms in other segments of the body call our attention to the possibility of this condition in the cervical spine.

Perhaps the greatest difficulty in diagnosis arises in differentiating the root pain of hypertrophic arthritis of the cervical spine from that of a new growth in the spinal cord or vertebral column. However, Elliott^{11*} reminds us that tumors in this area usually give distinct pressure symptoms as well as root pains, while Parker and Adson³³ point out that in the latter condition marked relief is ordinarily obtained by walking the floor at night or sleeping upright in a chair, whereas in arthritis, this only tends to aggravate the patient's symptoms. Moreover, where a tumor is present in the vertebra, the sedimentation rate is apt to be increased, and there will, as a rule, be some change in the serum phosphatase.

Four cases of especial interest have appeared in the foreign literature. These show how bizarre may be the type of onset and demonstrate how such variations can tend, at times, to confuse the picture. In two of the reports^{33,43} the patient's chief complaint was simply difficulty in swallowing, which was rather promptly relieved by the application of heat to the cervical spine. Another case⁷ was originally diagnosed as a meningitis due to a marked spasticity of the neck muscles. The fourth patient¹⁶ at first was thought to be suffering from an atypical form of amyotrophic lateral sclerosis because of the dragging of one leg and other difficulties of motor control. However, the fifth and seventh cranial nerves were never involved in the disease process, so that a diagnosis of chronic hypertrophic osteoarthritis of the cervical spine seemed most probable.

Treatment

It is nearly seventy years now since Anstie¹ stated in his paper before the Clinical Society of London that "it is worthwhile to remember that cervico-occipital neuralgias, by the consent of the best authorities, are decidedly hard to cure by any treatment." Many recent authors have been content to describe the disease process without advising as to the best procedure for relieving the patient. In general, three effective methods have been used:

1. *Physical Therapy*—Heat in all forms is recommended.

2. *Traction and Manipulation*.—Wagen-

thals⁴⁷ and Neviaser³² applied hyperextension to the spine along with applications of heat and secured gratifying results. Hanflig²⁰ used the Sayre head traction apparatus and proceeded to maintain the hyperextension in 5 of his cases by fitting a Thomas collar (all of the patients complained that their root pains began to return as soon as they were lowered to a sitting position). Some authors⁴² applied traction only in those few cases where the symptoms tended to persist following x-ray treatment or where there was some particular mechanical indication for it.

3. *Deep X-Ray Therapy*.—This gives the most satisfactory results in those patients not relieved by physical therapeutic measures. It was first used in 1932 by Bisgard⁵ who reported that he obtained his best results by repeated small doses. Two years later, Chaumet⁸ stated that radiotherapy in moderate dosage two to three times a week anteriorly and posteriorly to the cervical spine gives relief, as a rule, after a lapse of time varying from one to four weeks. "There is no question that x-ray is the best treatment by physical agents." Gauducheau¹⁵ reported recently on 27 cases treated with deep x-ray, of which 24 were cured or much improved by using the following method: 130 kilovolts, 6 mm. alum, 8 by 10, 25 cm., 50–200 r units given twice a week (total course 1,000 r units in air). He quoted Zimman as having obtained equally good results in 35 out of 41 cases by the same method.

Pfender³⁵ states that it is difficult to explain the curative action of the roentgen ray in these cases, "for it is certain that the osseous lesions are not affected by this treatment and that normal bone tissue cannot be restored. Furthermore, although the primary lesion lies in the osteophytes, they apparently play no part in the causation of pain; rather, it is the secondary lesion (i.e., the extension of the inflammatory process to the intervertebral foramina), which is the underlying cause of the pain."³⁰ We must assume, therefore, that these rays act on the connective tissue surrounding the nerve in its foramen and, by reducing the inflammation, relieve the pressure on the nerve itself. Decompression having taken place, the pain promptly disappears." It is his opinion that the early cases are more amenable to x-ray therapy and that comparatively small doses give the best results.

Some authors have advised large doses of brewers' yeast, while others—on the premise

* For references see Part I, January 15 issue.

FIG. 3. Original x-ray of cervical spine taken on Case 2 in July, 1937, at which time symptoms were relatively mild. Some thinning of the disk is apparent between C 5 and 6.

FIG. 4. X-ray taken fourteen months later, showing progressive thinning of same disk with an associated increase in patient's complaints.

expressed by Williams⁴⁹ that "there is no criteria by which involvement of the intrameningeal portion of the root can be differentiated from the extrameningeal part, for the involvement of either of these parts will be manifested as a radicular disturbance"—have given injections of thiamin chloride in large doses. Our experience has been that some patients will recover while taking large quantities of yeast, but the time period required for this improvement is in general about twice as long as for those patients who receive deep x-ray therapy.

Discussion

Hartsock²¹ maintains that there is little doubt that a great many cases of osteoarthritis of the cervical spine with radicular symptoms escape detection because of the fact that the x-ray findings, on first examination, have been reported as negative. Other authors,^{11,50} too, have called attention to the urgent need for considering the possibility of this condition even in the absence of any

definite x-ray changes. Turner and Oppenheimer⁴² cited several cases in their study of 50 patients who had a fully developed clinical picture without x-ray confirmation. All of these cases, however, had a distinct narrowing of one or more interspaces, as was so beautifully shown in their published photographs. A reproduction of one of Morton's²³ roentgenographs also showed this characteristic thinning of the intervertebral disk, but the author did not mention this finding as being of importance in making this diagnosis.

Parker and Adson,³³ moreover, were able to state conclusively, after careful pathologic studies on gross specimens, that "hypertrophic changes in the spinal column may be extensive and present for a considerable period of time without any x-ray evidence whatsoever of their presence." Consequently, in the early stages, even though the clinical symptoms may be very acute, a change in the cervical vertebrae will not always be demonstrable on the roentgenograph. It is only when the process has been present

for some time and permanent bony changes have resulted that the x-ray picture will show findings characteristic of chronic osteoarthritis.

We have a patient whom we have had under observation at infrequent intervals over a period of approximately four years, during which time the x-rays of her cervical spine (originally considered negative) showed progressive thinning of the disks with each increase in her clinical symptoms (Case 2) (see Figs. 3, 4, and 5).*

Case Report

Case 2—Mrs. E. M., aged 52, was first seen in July, 1937, complaining of pain in the back of her neck for a period of two years. Physical examination showed only a guarded position of head and neck, and an x-ray of the cervical spine was reported negative. The sedimentation rate was normal. She received physical therapy, massage, and exercises without appreciable benefit. Fourteen months later (September, 1938) she returned complaining of low back pain. An x-ray of the spine at this time showed only mild osteoarthritis of cervical and dorsal bodies with some lipping. Physical therapy and salicylates afforded temporary relief.

She disappeared then for over two years but returned in December, 1940, complaining of pain in both shoulders for a period of eight months. She stated that it had become more severe of late and was associated with frequent, shooting pains in the left upper extremity. She said: "As a rule, I'm up all night with it. If I can find a comfortable place in bed, I can go off to sleep for an hour or so, but the first thing I know, it wakes me up again. I've had a crink in my neck of late and my head aches when I get up in the morning. It isn't really like an ordinary headache; I hardly know how to describe it, for my head just hurts all over." Physical examination showed the same limitation of motion in the neck and left shoulder, but by this time there was some crepitus in her neck as well. An x-ray of the cervical spine taken at this time showed a considerable increase in the findings of osteoarthritis, particularly in the lower vertebrae with narrowing of the intervertebral spaces, especially C 5-6. The left shoulder was negative. Thereupon, deep x-ray therapy to the cervical spine was instituted, and the patient's symptoms had entirely disappeared after two weeks' treatment.

Another case is cited in the literature where the patient had a consistently negative x-ray for a period of eighteen months, during which time he was seen by several physicians. No definite diagnosis was made until he was examined by Gillespie¹⁶ who found a marked

FIG. 5. Film taken twenty-seven months after Fig. 4, showing a marked decrease in the thickness of the same intervertebral disk with consequent encroachment upon the intervertebral foramina and a sharp increase in patient's symptoms.

deformity of the cervical spine with hyperextension of the head. He did not wait for a positive x-ray picture to make the diagnosis of chronic hypertrophic osteoarthritis of the cervical spine but relied entirely on the history and physical findings. In 4 of our cases we found these factors so characteristic that we did not hesitate to make this diagnosis, even though it could not be confirmed at the time by x-rays.

Summary

1. The incidence of cases of chronic hypertrophic osteoarthritis of the spine associated with symptoms is apparently increasing both in private and clinic practice.
2. Thinning of the intervertebral disk can cause a unilateral or bilateral narrowing of the corresponding intervertebral foramina with resulting compression of nerve roots.
3. There is a predilection for the pathology to center in the lower cervical verte-

expressed by Williams¹⁹ that "there is no criteria by which involvement of the intrameningeal portion of the root can be differentiated from the extrameningeal part, for the involvement of either of these parts will be manifested as a radicular disturbance"—have given injections of thiamin chloride in large doses. Our experience has been that some patients will recover while taking large quantities of yeast, but the time period required for this improvement is in general about twice as long as for those patients who receive deep x-ray therapy.

Discussion

Hartsock²¹ maintains that there is little doubt that a great many cases of osteoarthritis of the cervical spine with radicular symptoms escape detection because of the fact that the x-ray findings, on first examination, have been reported as negative. Other authors,^{11,20} too, have called attention to the urgent need for considering the possibility of this condition even in the absence of any

definite x-ray changes. Turner and Oppenheimer⁴² cited several cases in their study of 50 patients who had a fully developed clinical picture without x-ray confirmation. All of these cases, however, had a distinct narrowing of one or more interspaces, as was so beautifully shown in their published photographs. A reproduction of one of Morton's²³ roentgenographs also showed this characteristic thinning of the intervertebral disk, but the author did not mention this finding as being of importance in making this diagnosis.

Parker and Adson,³³ moreover, were able to state conclusively, after careful pathologic studies on gross specimens, that "hypertrophic changes in the spinal column may be extensive and present for a considerable period of time without any x-ray evidence whatsoever of their presence." Consequently, in the early stages, even though the clinical symptoms may be very acute, a change in the cervical vertebrae will not always be demonstrable on the roentgenograph. It is only when the process has been present

Diagnosis

CLINICOPATHOLOGICAL CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

Conducted by Dr. Henry C. Fleming

History

The patient was an 80-year-old white woman admitted on December 15, 1941. She had suffered "heartburn," flatulence, and constipation for twenty years. She had been obliged to limit her diet to the simplest foods and had received relief from sodium bicarbonate and carthartics. During the past four years the patient had suffered five attacks of severe right upper quadrant pain, which radiated around to the flank and occasionally to the right shoulder. The attacks lasted as long as forty-eight hours. She entered the hospital because of severe right upper quadrant pain, which, however, did not radiate to the shoulder. Jaundice of the skin was noted on admission, along with the development of pain. The urine was dark but the stools were not clay colored. There had been a 35-pound weight loss during the four years prior to admission. The patient's father had died of carcinoma of the rectum. Appendectomy was performed about ten years prior to admission.

The patient was described as a remarkably well-preserved and well-developed 80-year-old white woman, moderately jaundiced. She was mentally clear on admission but was in acute pain. On admission the temperature was 101.2 F.; pulse, 96; respirations, 22; blood pressure, 102/56. The positive findings included icteric scleras, an edentulous mouth, and marked right upper quadrant tenderness with minimal muscle spasm. There was a right rectus incision below the umbilicus. Some observers described a mass in the right upper quadrant which was thought to be distended gallbladder. The heart was not enlarged, there was regular sinus rhythm, and the sounds were of fair quality. There were no thrills or murmurs present. There was a large scar on the left side which was the result of an old burn. There was no clubbing, cyanosis, or edema of the extremities. The rectal examination was negative. The clinical impressions at the time of admission included acute empyema of the gallbladder, common duct stone, and metastatic carcinoma of the liver.

Laboratory Findings.—The urinalysis on admission showed a specific gravity of 1.014 and a 2 plus albumin. The urine was positive for bile. A day later, tests for urobilin and urobilinogen were negative. The red blood count was 5,100,000 with 100 per cent hemoglobin, the white blood count was 17,350 with 84 per cent polymorphonuclears. On December 17 the blood nonprotein nitrogen was 60; the blood sugar, 95. The icteric index was 65; the van den Bergh, direct, showed an immediate reaction, and the blood cholesterol was 211.

The pain gradually subsided, but the temperature rose to 103.8 F. on the fifth hospital day, at which time the jaundice had increased and the white blood count was 17,300. Patient began at this time to sink gradually into a comatose state, but despite her condition it was thought that surgery would offer the only hope of relief. The patient was operated on through an upper right rectus incision but, owing to the poor condition of the patient, cholecystostomy was done. The common duct was not explored. The patient died on December 22, 1941, on the seventh hospital day.

Discussion

DR. HENRY C. FLEMING: Gentlemen, you have all heard and probably read the protocol. I shall ask Dr. Washburn to comment.

DR. ARTHUR L. WASHBURN: I suspect a ball valve stone of the common bile duct with empyema of the gallbladder. The red blood count and hemoglobin are against carcinoma. I feel that the increased white blood count and the temperature rise are perfectly consistent with common duct stone. The various digestive difficulties that the patient had had for twenty years were the symptoms of chronic cholecystitis. The severe attacks of pain were typical of ball valve stone.

DR. HENRY C. FLEMING: Did the patient have a small or large gallbladder?

DR. ARTHUR L. WASHBURN: The patient, according to description, probably had a distended gallbladder. She had had five

brae, since these are more subject to trauma, and the foramina in this area are smaller in proportion to the size of the emerging nerve roots.

4. The outstanding characteristic of this syndrome is aggravation of all symptoms by any movement of the spine (particularly by hyperextension) and by coughing, sneezing, or straining.

5. Most root pains ("peripheral neuritis") associated with aching and soreness of the shoulder muscles and aggravated by motion of the neck are due to an osteoarthritis of the cervical vertebrae.

6. Every case presenting complaints of pain or limitation of motion in one or both shoulders warrants a thorough study of the cervical spine, particularly if enough local pathology has been found in the shoulder to account for the symptoms but where no response has been obtained to specific treatment to that shoulder.

7. No direct relationship has been found with regard to age, sex, race, body weight, type, or the general state of the patient's health.

8. Radiculitis can involve any group of nerve fibers contained in any nerve root—motor, sensory, or sympathetic—and the symptoms, unilateral or bilateral, may reflect evidence of irritation or loss of function, either partial or complete.

9. Chronic osteoarthritis of the cervical spine may at times have a bizarre onset and so should be kept in mind constantly as a possibility in the differential diagnosis of pains in the head, neck, chest, and upper extremities.

10. Chronic arthritis of the cervical spine is a frequent cause of a characteristic, occipital, early-morning headache (40 per cent of our cases). This condition can be diagnosed even in the absence of definite

x-ray findings and the proper therapy instituted.

11. Arthritis in the cervical spine can constitute an "irritation focus" for neuralgias of the cranial nerves and thereby explain such unusual symptoms as unilateral sore throat and earache not associated with local pathology.

12. Osteoarthritis of the cervical spine can cause precordial pain which, at first, may be indistinguishable from that due to organic heart disease, but a careful history and physical examination, together with electrocardiographic and x-ray studies, will serve to differentiate a radicular pain from that of visceral origin.

13. In the differential diagnosis of pain in the neck, shoulder, or upper extremity, great care must be exercised and a wide variety of conditions must be considered.

14. Hypertrophic changes in the cervical spine may be extensive and present for a considerable period of time without any x-ray evidence whatsoever of their presence. This fact has been proved by careful examination of gross specimens, as well as by clinical studies with serial x-ray pictures.

15. Many cases are completely relieved by physical therapy, salicylates, and large quantities of yeast, but some more resistant ones will need small doses of deep x-ray.

16. Roentgen therapy is an efficient aid in relieving pain. It reduces the inflammation that surrounds the nerve in its foramen and thereby relieves the pressure on the nerve root. Early cases are most amenable to treatment and comparatively small doses give the best results. In a few, the pain may persist even after this therapy, and traction with maintenance of hyperextension will be required before complete relief is effected.

133 East 58th Street

STATISTICS FROM ENGLAND

The marriage rate for 1940 in England was 30 per cent higher than prewar levels, according to the Metropolitan Life Insurance Company, but during the first six months of 1941 the birth rate in England's cities fell off 20 per cent. Infant mortality this year is high in England, because communicable diseases have been prevalent. Measles was abnormally prevalent in the first half of 1941 and whooping cough also. Diphtheria cases were increasing to a lesser extent. These conditions improved considerably during the summer, however, aside from the whooping cough situation.—*Medical World*

SLIP OF THE TONGUE

"The answer to the question of why intelligent, well-educated people misplace words would involve a long philosophic discussion of what are considered in the Freudian literature as 'slips of the tongue,'" *Hygeia, The Health Magazine* states in answer to an inquiry as to whether such "slips" are a remote sign of insanity. "There are many different types of slips," the article says, "some having rather obvious meanings, while others are obscure and little understood. Such 'slips' or the misplacement of words are common and bear no established relation to mental disease."

and contracted gallbladder rather than the distended one of empyema.

I believe the increasing jaundice indicated obstruction to the flow of bile—not common in empyema until well-developed cholangitis or hepatitis occurs. And if obstruction was the explanation of the jaundice, that frequent finding of common duct stone was the probable answer.

You will recall that Corvoisier pointed out to us half a century ago that obstruction of the common duct by stone is far more frequently associated with a small rather than with a large gallbladder. This assertion was predicated upon the belief that the stone was born in or occupied the gallbladder and there created the inflammatory process that resulted in fibrosis and contraction. The irregular mass in the right upper quadrant could readily be omentum, which we so frequently find adherent to or overlying a chronic gallbladder.

The weight loss, pointed out by Dr. Trubek, probably indicated diminished fat digestive ability. The coma was probably the result of cholemia, uremia, asthenia, and dehydration.

Time precludes further elaboration but, as my impression of this being a case of chronic cholecystitis with common duct stone has been challenged upon the assumption that such did not explain the pain, I should like to state that it is my impression that pain of variable radiation and intensity may occur in gallbladder disease regardless of the existence or nonexistence of stone.

DR. KENNETH M. LEWIS: I think that there are a few things about this case besides the obstructive signs. Why did the patient go into coma? Cholemia cases do not go into coma so rapidly. The blood nonprotein nitrogen was 60; the patient was in deep coma and was markedly dehydrated. The high red blood count, white blood count, and increased temperature could be accounted for by the marked dehydration. The blood nonprotein nitrogen before death had risen to 100. Whether this patient was in uremia, we do not know. That might have been another factor besides the gallbladder disease. Postoperatively, the patient received whole blood and plasma and continuous infusions of 5 per cent glucose in saline. Regardless of the above therapy the patient remained in coma. Because of the signs of obstruction (jaundice) the patient was a poor operative risk. The operation was performed under local anesthesia (field block). We thought that the patient had an

empyema of the gallbladder, but plastered over the gallbladder was the omentum and stomach. There were dense old adhesions. By careful dissection, a small contracted gallbladder was found with no evidence of acute inflammation. The mucosa was bile-stained. A tube was inserted into the gallbladder; cholecystostomy was performed to sidetrack the bile flow. The common duct was not exposed. Postoperatively, it was noted that the bile drained freely. A transfusion of 500 cc. of whole blood was given. Plasma and the infusions of 5 per cent glucose in saline were continued. The circulation was in a good state. The patient died thirty-six hours after operation.

Pathology

DR. MAX WILHELM JOHANNSEN: Necropsy was performed twenty-four hours after death. The relevant findings were as follows: Intense jaundice was noted over the entire skin. There were also present many ecchymotic areas. A recent right rectus operative incision held together by three retention sutures was found. The peritoneal cavity did not contain any fluid, but the greater omentum showed many recent adhesions in the proximity of the operative site and many old fibrous adhesions in the vicinity of the gallbladder bed. A rubber drain extended from the gallbladder bed into the operative wound of the anterior abdominal wall.

The liver, pancreas, stomach, and duodenum were removed in total. The portal vein and its tributaries were free of any pathology; the biliary ducts were isolated; the common duct was slightly dilated in its distal one-half; and in the midportion of the common duct, a large, round, rough calculus was found firmly impacted. This stone measured $1\frac{1}{2}$ cm. in diameter. Above this point of obstruction the common duct was dilated and led into the patent cystic duct, which, in turn, led into the markedly narrowed and shrunken gallbladder.

On sectioning, the liver itself showed, in addition to obvious bile staining, slight lobulation. The pancreas was natural. The lungs showed considerable gray-white granular patches, particularly marked in the lower lobes. The spleen was slightly larger than normal and mushy to the touch. Microscopically, there was revealed a slight biliary cirrhosis with mild acute cholangitis and many milary abscesses. The kidneys failed to reveal any pathology, either grossly or micro-

episodes of pain and the mass felt was exquisitely sensitive—it might have been distended gallbladder.

DR. HENRY C. FLEMING: What was the gradual loss of weight due to?

DR. ARTHUR L. WASHBURN: This case was one of gallstone with empyema of the gallbladder. There might have been coexisting neoplasms.

DR. BEECKMAN J. DELATOUR: We are dealing with an obstructive type of jaundice. I believe there was a degenerative change of the liver, there was some evidence of hepatitis. The patient gave a history of long-standing digestive disturbances. This underlying infectious process is borne out by the elevated white blood count and the temperature. The question of malignancy then arises, but there is tenderness in the region of the bladder only in the final stages of malignancy. Dr. Llewellys Barker of Johns Hopkins has stated that physical diagnosis of the abdomen is the most difficult. In malignancy of the gallbladder there is a low white blood count but an increased number of polymorphonuclear cells. That generally applies to carcinoma of the abdomen. There was a high total white blood count in this case. In cases of acute gallbladder disease it is important to operate before the jaundice sets in.

DR. ARNOLD KOFFLER: Operative procedure was indicated because of definite attacks of pain, evidence of obstruction, the mass in the upper part of the abdomen, and the high temperature. I do not feel that this patient had an empyema of the gallbladder. I feel that the patient had a common duct stone with obstruction.

DR. MAX TRUBEK: The attacks resembled those of biliary colic. The patient had been on a low fat diet for twenty years and, that, with old age, probably accounts for the weight loss. Pancreatitis should be considered as a differential in this case—also carcinoma of the pancreas. The acute cholangitis accounts for the septic state.

DR. HENRY C. FLEMING: What was the violent attack of pain due to?

DR. MAX TRUBEK: The pain was due to the stone either in the cystic duct or common duct. Carcinoma of the pancreas can give such colicky pain.

DR. MENNASCHE KALKSTEIN: The exact anatomic diagnosis cannot be made. In the presence of unexplained persistent jaundice that is not receding, operation is the only procedure and the sooner it is done the better.

DR. ELLIOTT HOCHSTEIN: Dr. Robert Zollinger, of Boston, in various experiments on the localization of pain in the gallbladder, has made the following observations: If the gallbladder is distended, there is a feeling of fullness in the epigastrium. Only when the common duct is involved do the patients get pain. If involvement is in the cystic duct, there is no pain.

DR. EMANUEL APPLEBAUM: I was impressed by the lack of discussion in regard to the preterminal coma. Patient had marked impairment of liver function. Clinically, that was impressive.

DR. ZACHARY SAGAL: The patient was well nourished; the weight loss was not significant. There was definite evidence of sepsis as evidenced by the high white blood count and the temperature elevation. The attacks of pain were those of gallbladder disease. Deep palpation could not be done as there was extreme tenderness in the right upper quadrant. The patient should have been operated on sooner. The fine points of diagnosis were taken too much into consideration. Surgery was indicated when the tentative diagnosis was made. I believe she had an empyema of the gallbladder.

Summation

DR. HENRY C. FLEMING: Significant features of this case were not only the tenderness in the right upper quadrant, believed by several to be due to empyema of the gallbladder, jaundice, elevated temperature, leukocytosis, bile in the urine, and positive van den Bergh, but also the long-standing digestive history, 35-pound weight loss, and five severe attacks of right upper quadrant pain with variable radiation to loin and shoulder, flatulence, nausea, etc. I believe these signs to be due to disease of the biliary system with probable liver involvement, but the correct label I believe is somewhat a matter of conjecture. I do not think, however, that the weight of evidence sustained a strong suspicion of empyema of the gallbladder, for I believe that the mass we felt in the right upper quadrant was of irregular surface and definitely corrugated yet not hard enough to suggest stone. It certainly was not the smooth, rounded viscus of a gallbladder; in fact, I first suspected the possibility of malignancy. And in this case we have a history of twenty years of digestive disturbances with at least five acute attacks of severe pain, etc. This suggests chronicity. And if this be correct we are probably dealing with a thickened, fibrosed,

JEAN OLIVER, *President*
JOHN M. PEARCE, *Secretary*

A Case of Weber-Christian Disease. Dr. Robert Kritzer (*by invitation*)

Twenty-two cases of this condition, known also as relapsing febrile nodular nonsuppurative panniculitis, have been reported. Of the 2 deaths due apparently to this disease, this is the first in which an autopsy was performed.

A 34-year-old Jewish housewife was admitted several times to the Presbyterian Hospital for a twenty-nine-month-old illness, characterized by crops of enlarging and coalescing, variably tender, subcutaneous nodules in her thighs, buttocks, and later in her upper extremities; by fever of 101 to 103 F.; and by malaise and weakness. The panniculus adiposus underwent atrophy at the sites of old lesions. The skin over some was firm, red, scaly, and ulcerated terminally. The last weeks were marked by large numbers of new

skin lesions, by a temperature of 104 F., by delirium, and by chemical evidence of rapidly increasing liver damage.

At autopsy the essential features of the skin lesions previously described were found—namely, a nonsuppurative exudate in the panniculus, collapse of many of the fat cells, necrosis of the exudate, lipophagocytosis, and entry into the adipose cells of wandering phagocytes and lymphocytes, both in the exudate and within the adipose cells. Internal fat depots showed no striking changes. The liver was fatty; the spleen was enlarged. There were widespread acute necroses of the liver, chiefly central, and of the spleen. Fat emboli were found in the lungs, and many of the cells in the adrenal cortex showed hydropic degeneration.

A Case of "Temporal Arteritis." Dr. E. E. Sproul (*by invitation*)

A male American, aged 68, was under treatment for diabetes mellitus and for precordial pain, which was thought indicative of coronary stenosis. He suddenly developed severe throbbing pain in the temporal regions, with prominence and tenderness of both temporal arteries which subsequently lost their pulsations. A white count of 17,000 with 52 per cent polymorphonuclear neutrophils and a sedimentation rate of 116 mm. per hour were the only abnormal laboratory findings. His symptoms and physical signs referable to the head subsided during a period of eight weeks, but precordial pain recurred and he died as cardiac failure and lobular pneumonia supervened.

The outstanding findings on gross inspection of the organs were the infarcts of the myocardium associated with advanced coronary stenosis and an extensive organizing pneumonia with superimposed purulent bronchitis. The aorta appeared diffusely dilated and was inelastic. There was moderate intimal sclerosis, and a few areas showed fine longitudinal

wrinkling. The media was frequently thin and appeared to be extensively vascularized. The adventitia was delicate. All of the main branches were narrowed and showed medial discoloration with hemorrhage. The adventitia of the carotid arteries was thickened.

Histologic study revealed a profound change affecting the aorta, as well as the carotid, innominate, subclavian, pulmonary, celiac, mesenteric, renal, and iliac arteries. The cerebral arteries could not be examined. There was extensive caseous necrosis of the media with much nuclear fragmentation and disruption of fibers. At times, the degeneration was diffuse; in other areas, discrete and affecting only a portion of the wall. Usually, a cellular reaction including lymphocytes, plasma cells, and multinucleated giant cells was a prominent feature. The intima was frequently thickened by recently proliferated connective tissue. The adventitia showed minimal thickening and mononuclear cell in-

scopically, which might explain the elevated nonprotein nitrogen.

To summarize, this case was one of common duct stone leading to complete obstruction of the biliary outflow and in which an ascending cholangitis lead to the formation of miliary abscesses within the liver parenchyma. I heartily agree with Dr. Kalkstein who stated that surgery was the only type of treatment in a case with obstructive jaundice, regardless of what the clinical impression might have been. A few days ago an autopsy was done on a patient who was operated on for complete obstruction of the biliary tract with preoperative diagnosis of carcinoma of the head of the pancreas. Here, two stones were found to obstruct the biliary tract, one in the common duct and one in the hepatic duct. A year and one-half ago an autopsy was done on another patient who, five years before death, was operated on for what was thought to be carcinoma of the head of the pancreas. In this patient a cholecystogastrostomy was performed and the patient got well. At the time of operation this patient had complete obstructive jaundice caused by an interstitial pancreatitis and obviously not by carcinoma, otherwise he would not have survived for five

years. No evidence of carcinoma was found at necropsy. Interestingly enough, a cholecystogastrostomy was closed and the common duct emptied freely into the duodenum. The last case, I recall, was a patient in whom a cystic duct stone pressed on the hepatic duct and this caused obstruction. Again, there was obstruction with subsequent inflammation leading to severe jaundice. Again the diagnosis of carcinoma of the pancreas was made. Possibly, this man might have been saved if he had been operated on early.

Diagnosis

Choledocholithiasis with obstructive jaundice.

Biliary cirrhosis with mild acute cholangitis and focal abscess formation.

Organizing perihepatitis.

Mild atherosclerosis of mitral and aortic valve and aorta.

Lobular pneumonia.

Congestion and edema, both lungs.

Emphysema.

Pleural effusion—right.

Acute splenitis.

Recent right rectus incision.

Postoperative absence of appendix.

HEALTH EDUCATION LECTURES

A course of lecture conferences on the scientific foundation of health education has been arranged for the health educators of New York City by the Subcommittee on Scientific Sessions of the Health Education Section of the Welfare Council, New York. This subcommittee consists of Dr. Iago Galdston, New York Academy of Medicine, chairman, Miss Hazel Corbin, Maternity Center Association, Miss Lucy Gillett, Community Service Society.

The series consists of addresses by the following speakers:

DATE	NAME	SUBJECT
January 30	Dr. J.B. Youmans, assistant professor of medicine, Vanderbilt Medical School, Nashville, Tennessee	Nutrition and Health Education
February 26	Dr. John Romano, associate in medicine, Peter Bent Brigham Hospital, Boston	Mental Hygiene

DATE	NAME	SUBJECT
March 25	Dr. Bernhard J. Stern, Department of Sociology, Columbia University, New York City	Sociology
April 30	Mr. Philip Lennen, president, Lennen & Mitchell, New York City	Instrumentalities of Education and Propaganda
May 28	Dr. Perrin Long, Johns Hopkins University, Baltimore	Hygiene—Public Health

Health educators who are working in special fields will be given an opportunity to check and survey the broad field of medicine on which health education is founded.

The lecture conferences are being held at The New York Academy of Medicine, 2 East 103rd Street, New York City, from 3:30 to 5:00 P.M., and admission to the series of meetings may be procured by writing Dr. Iago Galdston, Health Education Section, Welfare Council, 44 East 23rd Street, New York City.

vated from the sputum. To date the disease has been diagnosed at autopsy in 31 cases, antemortem in 16 cases. In the antemortem cases the diagnosis was made by biopsy in 4 cases, by culture in 10 cases, and by microscopic examination of the blood in 2 cases.

Van Pernis, of Chicago, produced an antigen from a culture of the organism which gave a combined immediate and delayed skin reaction in his patient.

The geographic distribution of cases to date is as follows: United States, 35 (Maryland 1, Virginia 2, Florida 1, Alabama 1, Ohio 1, Michigan 8, Indiana 3, Illinois 2, Kentucky 2, Tennessee 6, Minnesota 1, Iowa 1, Missouri 3, Texas 1, California 2); Canal Zone, 3; Honduras, 1; Brazil, 3; Argentina, 2; Philippines, 2; Java, 1. Thus far, all cases have been in persons living in small towns or rural areas. The case in a dog was from Tennessee; that in a ferret was from Illinois.

The differential diagnosis of histoplasmosis from leishmaniasis is based upon the presence of a capsule and the absence of a blepharoplast in histoplasma and in the absence of a capsule and the presence of a blepharoplast in leishmania.

Histoplasma capsulatum exists in the yeast-like form in the warm-blooded host. Upon cultivation aerobically at room temperature, it develops a white cottony colony with aerial hyphae on which develop tuberculate chlamydospores; when cultured at 37 C. on blood agar sealed with paraffin, the yeastlike form develops. Conant has placed the organism in the family Moniliaceae of the fungi imperfecti.

Discussion

DR. JEAN OLIVER: I want to ask if there has been any connection established between these organisms from the mycologic standpoint with the Oidiomycetes group, the Oidium coccidioides, and so forth. I am thinking of this in particular because the latter shows mycelian form in the cultural growth but never in the tissues, which seems to be characteristic of this mold.

DR. HENRY E. MELENEY: I am not enough of a mycologist to know the classification of these organisms, but apparently it belongs to a different family from *O. coccidioides*. The appearance of the organism is somewhat the

same, but I believe there are definite differences in size, if not in structure.

DR. OLIVER: It is interesting that they both show these two types of growth in culture and in the tissues.

DR. FREDERICK SUMMERILL: Since Dr. Meleney mentioned that the nearest to this part of the country any case has been reported is Maryland, I should like to cite that last summer a veterinary physician autopsied a cat and brought the organs in formaldehyde to my laboratory in Middletown, New York, where sections were made. I found this organism in the mesenteric lymph nodes and in the lungs. There were ulcerations in the small intestines, markedly enlarged lymph nodes in the mesentery, and also peculiar inflammatory areas of a pseudocaseation distributed throughout both lungs. I later conferred with the Cornell University School for Veterinary Medicine, and they said that it was the first case of this kind affecting a cat as far as they were able to determine.

DR. MELENEY: That is interesting because it was in *The Cornell Veterinarian* that the case in a ferret was described.

DR. IRVING GRAEF: I wonder if Dr. Meleney will say a word about the portal of entry and the mode of transmission for human cases.

DR. MELENEY: Anything I say, of course, is speculative. I think this fungus must exist saprophytically in nature, although it has never been found. I think one portal of entry may be through an abrasion of the skin. It also undoubtedly enters through the mouth and may go through the respiratory tract to the lungs primarily or may cause local ulceration in the pharynx. There was 1 case at Vanderbilt University diagnosed as Hodgkin's disease which had an ulceration in the mouth. There have been several others, 1 with an apparently primary lesion in the nose, and 2 in which there were polypoid growths on the larynx. When swallowed, it may produce ulcers in the small or large intestine and may enter the mesenteric lymph or blood vessels, producing the systemic disease. The possibility of insect transmission should not be ignored. Some biting fly might transfer it, but we do not know anything about a reservoir host, and I think it is much more likely to be acquired by one of the other routes described above.

filtration. None of the vessels was thrombosed.

It was believed that the change resembled that described in the temporal arteries by Horton, *et al.* (Horton, B. T., Magath, T. B., and Brown, G. E.: *Proc. Staff Meet., Mayo Clinic* 7: 700, 1932) and designated as "temporal arteritis." About 24 cases in all have reached the literature, but in the majority of instances there has been complete remission of symptoms. Four cases in which necropsy was performed have recently been described (Gilmour, J. R.: *J. Path. & Bact.* 53: 263, 1941). The lesions were similar to those observed in this case.

Additional staining by the methods of Gram, Levaditi, and Brown, as well as carbol-fuchsin stains, failed to disclose an etiologic agent. There were no fungi or molds. This has also been true of the biopsy specimens reported and the few necropsied cases. All cultures, agglutination tests, and animal inoculations have been fruitless. The Wassermann and Kline tests were usually negative. The etiology of this extensive granulomatous change affecting the large arteries exclusively remains undisclosed.

Discussion

DR. ALFRED PLAUT: The rarity of this

disease warrants the reviewing of another case that lately came under observation. The clinical history was the usual one: the patient was a woman, aged 63, with a history of variegated pains for months and fever and lassitude for several weeks. No pulsation could be felt in the temporal arteries. This was easily explained by the sections which showed that the artery was entirely filled with a granulomatous structure leaving not the slightest remainder of a lumen. Giant cells were numerous, and only some of them could be explained as foreign body giant cells, formed under the stimulus of fragmentation of elastic lamellae.

While phlebitis is frequent and rather uniform in the histologic picture, arteritis is rare and reveals a multiplicity of pictures. In the last issue of the *English Journal of Pathology and Bacteriology* (Gilmour, J. R.: *J. Path. & Bact.* 53: 263, 1941), 4 cases of chronic giant-cell arteritis have been published. Granulomatous masses in these cases occupied parts of the aorta and its large branches, especially in the head. Mention should be made also of the case of arteritis published from the Pathology Department of Columbia University (Sproul, E. E., and Hawthorne, John J.: *Am. J. Path.* 13: 311, 1937).

Histoplasmosis. Dr. Henry E. Meleney (by invitation)

Histoplasmosis was discovered by Darling in Panama in 1906 when he was in search of cases of visceral leishmaniasis. He considered it to be a protozoan disease, but in 1912 Rocha-Lima established it as a fungus disease. It is essentially a disease of the reticuloendothelial cells, but differs from leishmaniasis in its tendency to produce tubercle-like necrotic lesions. Forty-seven human cases have now come to my attention; of these, 11 were discovered up to 1934, and the remainder were discovered or reported as follows: 6 in 1939, 16 in 1940, and 14 in 1941. In addition, 1 probable case was found in a ferret and 1 proved case in a dog. A review of the subject was published in 1940 (Meleney, H. E.: *Am. J. Trop. Med.* 20: 603-616).

The clinical types of the disease are (1) a generalized infection with parasites in the reticuloendothelial cells in all parts of the body; (2) a lymph node syndrome simulating aleukemic leukemia, Hodgkin's disease, or lymphosarcoma; (3) a skin disease manifested by single or multiple lesions; (4) pri-

mary infection of the nasopharynx or larynx with extension into the intestines or lungs or throughout the body; (5) a lung infection with or without further extension. The distribution of the parasites in the body depends upon the portal of entry and the extent of spread. Cases in infants often show no necrotic lesions. Some necrotic lesions simulating miliary tubercles, sometimes with giant cells but without epithelioid cell formation, are frequently found unassociated with parasites but probably represent true lesions of the disease. Tuberculosis, either of the lungs or with miliary spread, is frequently associated with the disease. A peculiar localization of the infection is in the adrenals, 3 cases having been found in which these organs were involved exclusively, with large caseous areas surrounded by many parasitized cells. Ulcers of the small and large intestines surrounded by parasitized cells have been described in several cases, with perforation of the ileum in 1 case. The prostate gland was involved in 1 case, and in 1 case the organism was culti-

Dr. Wilens whether he studied or used any other foreign substance, such as dye or India ink, injected into the animals that had these cuffs on the artery in order to see whether there was any localization other than of cholesterol.

DR. WILENS: I am sorry I did not attempt to do that, although I think it might be an important thing to try.

DR. MILTON HELPERN: I should like to ask whether the artery can dilate after the cuff is placed on it, or does the cuff prevent dilation? The inability of the artery to dilate because of the cuff would amount to a relative constriction of the vessel with an increase in the velocity of blood flow through it in systole.

DR. WILENS: I cannot state absolutely whether or not complete dilatation was possible. However, as I say, an attempt was

made to choose a cuff that was approximately equal to the size of the vessel in systole. I am sure a certain amount of pulsation occurred within the cuff, because we could actually see it after we put it on. In no instance was there thrombus formation; nor was the vessel occluded, which would have happened if there had been any great degree of constriction.

After the cuffs became enclosed in fibrous tissue the movements of the artery wall within the cuffs were probably restricted, but after all this was the main object of the experiment. I wish to emphasize again that no attempt was made to avoid injury to the artery wall at the site of application of the cuffs. I did, however, wish to produce an injury that was constant in all cases, so that any marked deviation in the amount of lipid deposited could be explained on some other basis.

HANDBOOK ON MEDICAL SERVICE PLANS

The Ohio State Medical Association has just issued a Medical Service Plans Handbook containing recommendations to its component societies "as to proper procedure for starting voluntary nonprofit medical care plans under the provision of the Ohio Enabling Act."

Procedures for the establishment of medical service plans are set forth. These are specific and complete. Included also is the resolution adopted by the House of Delegates relating to the Ohio Enabling Act and a copy of the Act itself.

A valuable feature of the handbook is the "must" and "optional" reading list. The list includes books and articles on medical economics from every point of view.

The handbook, which is being provided the president and secretary of each county society, shows the care and thought that have gone into its preparation. The Ohio State Medical Association is to be commended for a task well done.

THE NEW YORK TUBERCULOSIS AND HEALTH ASSOCIATION

... will hold its fortieth annual meeting on Monday, March 2, at the Hotel Pennsylvania, New York City, following its annual conference on tuberculosis, which will be held jointly with the Tuberculosis Sanatorium Conference of Metropolitan New York, beginning at 9:30 A.M.

Dr. Bruce H. Douglas, president of the National Tuberculosis Association, Dr. Charles J. Hatfield, president of the Philadelphia Tuberculosis and Health Council, and Dr. Edward S. McSweeney, chairman of the tuberculosis committee of the New York Tuberculosis and Health Association, will be the speakers at the luncheon meeting at which Dr. J. Burns Amberson, Jr., president of the New York Association will preside.

Tuberculosis and national defense will be discussed by Dr. Douglas, who is also Health Commissioner of Detroit, while Dr. Hatfield will speak on "Tuberculosis—Retrospect and Prospect." Dr. McSweeney will report on "Another Year of Tuberculosis Work."

NEW YORK SOCIETY FOR CLINICAL OPHTHALMOLOGY

The meeting on March 2 of the New York Society for Clinical Ophthalmology will consist of a panel discussion on "Disturbances of Ocular Motility" by Dr. George P. Guibor, Dr. Le Grand H. Hardy, Dr. Luther C. Peter, and Dr. James W. White. The coordinator will be Dr. Isadore Givner. The panel discussion will be

preceded by a paper on "Neuro-ophthalmologic Aspects of Eye Muscle Disorders" by Dr. Israel S. Wechsler.

The meeting will be held at the Squibb Hall, 745 Fifth Avenue, New York City, and all ophthalmologists are cordially invited to attend.

The Distribution of Intimal Atheromatous Lesions in the Arteries of Rabbits on High Cholesterol Diets. Dr. Sigmund L. Wilens (*by invitation*)

A new theory is advanced to account for the localized nature of lipid deposits in atheromatous lesions of arteries and for the tendency of such lesions to appear at fairly constant places, such as at points of bifurcation in the early stages of their development.

This theory expresses the belief that the accumulation of lipids at a focal point is not due to the excessive penetration of these materials into the intima directly from the blood stream at the site of the plaque but rather that they represent pooled deposits that are built up by the movement of lipids within the arterial intima as a whole to places at which their permanent arrest is favored. The impetus to this movement is believed to be imparted to the lipid droplets by the pulsation of the arterial wall. The direction of movement is believed to be from points of relatively great mobility to points of relative fixation or to points where impassable barriers are present such as the orifices of arterial branches.

By applying this theory it is possible to account for most of the observations that have been made as to the distribution of intimal plaques under different circumstances and at various age periods.

The following data are presented in support of this theory:

Intimal plaques are actually found at points of greatest fixation in the human aorta. These points represent areas that exhibited impaired elasticity early in adult life (Wilens, S. L.: *Am. J. Path.* 3: 811, 1927). The impairment of elasticity occurs regardless of whether or not intimal plaques are formed. The alteration in elasticity in itself is therefore not the cause of plaque formation.

Portions of the carotid and femoral arteries of rabbits were immobilized by having cylindrical silver cuffs applied to them. When the rabbits were subsequently fed cholesterol, lipids tended to accumulate selectively at the zones of immobilization. It was shown that this tendency was not the result of the local injury produced by the cuff alone, but rather that it was a measure of the total amount of lipid deposited in the artery as a whole. The occurrence of lipid-free zones at either side on the cuffed regions and the piling up of lipids against zones of intimal fibrous proliferation in the intima at the margins of the cuff were also features that were interpreted as favoring the theory advanced.

A fairly constant orientation of noncrystalline anisotropic lipid at the margins of natural human atheromatous lesions was observed. Reasons are advanced for believing that this type of lipid is composed largely of cholesterol esters and that it represents lipid that has been recently acquired by the plaques. The predominance of this lipid fraction at the periphery of the plaques is represented as the result of its convergence from the neighboring intimal tissues.

It is pointed out that substantiation of the theory advanced would suggest that the artery wall plays only a passive role in determining the ultimate disposition of intimal plaques. Furthermore, it would render it unnecessary to hypothecate that antecedent injury to the artery wall is necessary for localized deposits of lipid to form.

Discussion

DR. JEAN OLIVER: I have some recollection of experiments done by Klotz a great many years ago in which he put clamps on the aortas of rabbits. I think that it was perhaps before the time of cholesterol arteriosclerosis. As I remember, he got some sort of a lesion related to the clamp. I believe that his explanation was that the area where the clamp had been was one of stress and strain—which is, as you say, not specific in its analysis. Do you remember these experiments, and did he find collections of lipid?

DR. SIGMUND L. WILENS: There are innumerable experiments of that type, most of them antedating the cholesterol feeding era. Few claims have been made that by direct injury to the artery alone one can get much of an atheromatous lesion. Such lesions as are produced are generally devoid of lipids. I do not recall the specific paper you had in mind.

DR. JOSEPH VICTOR: I should like to ask whether there was any compression of the artery at the site of the clamping.

DR. WILENS: The clamps were made in various sizes from 1 to 5 mm. in diameter, and when the artery was exposed I did the best I could to pick one that was approximately the same as the external diameter of the clamp. I am confident that there were no marked degrees of compression and that the vessel, when opened at the time of sacrifice, did not show narrowing or constriction of the cuffed zone.

DR. CASPAR G. BURN: I should like to ask

industrial gas masks. The canister must contain (1) sorbents that will take out acid gases, such as phosgene and chlorine, and vapors, such as mustard gases and blister gases, and (2) an efficient filter for removing the irritating smokes. Previous to the use of masks, only gauze pads soaked with neutralizing chemicals and tied over the nose and mouth were used and, in the absence of masks, may have to be resorted to in case of attack.

In addition to needing masks for respiratory protection from gases, special clothing is needed by special service personnel such as firemen and others who may be required to remain in areas infested with blister gas or similar gases for duties such as decontamination work, fire fighting, and making utility repairs. These persons must be completely protected—no skin part can be exposed. Fabrics that are either impervious to the gas or are impregnated with substances that will take out the gas are available for clothing of this nature. These no doubt will be made available. Oilskin coveralls, oilskin gloves, and rubber boots are examples.

Special Treatment Center for the Chemical Warfare Casualties

A gas-cleansing center should be provided particularly for victims of blister or vesicant gases. Those suffering from lung irritants and other gases may be given emergency treatment at first-aid stations. A continuous-flow method of handling contaminated personnel has many advantages and permits the passage of personnel through a series of rooms or sections where they are cleansed and then evacuated from the opposite end in such a manner that no individual is subject to further contamination.

Liquid mustard gas contacting the skin quickly penetrates and persists unchanged in the tissues for many hours. This fact has a definite bearing on any attempts at the early treatment of mustard gas burns. The skin effects following exposure to the vapors of mustard gas are usually insidious and may be delayed for two or three hours and often longer. Then the eyes become reddened and the skin burns and itches, especially in the moist sweating areas. The skin lesions may vary from simple erythema to extreme blistering, deep necrosis, and sloughing. The skin lesions heal slowly and are frequently complicated by severe secondary infections.

Corneal ulceration may follow the initial conjunctivitis, and severe inflammation of the nasal and pharyngeal mucosa, larynx, trachea,

and bronchial tubes may result if the person has breathed in the gas. The bronchitis is accompanied by bronchopneumonia in a high percentage of cases. Nausea and vomiting, associated with epigastric pain, occur and may be persistent. Extreme nausea, vomiting, diarrhea, and collapse result from ingestion of contaminated food or liquids.

Since a delay of a minute or two in the case of liquid contamination with mustard gas or a delay of from ten to fifteen minutes following exposure to the vapors of mustard gas is serious, the speedy and complete removal of all contaminated clothing is essential. Decontamination of clothing may be accomplished by long exposure to windy air, by boiling, by chlorination, or by the action of bleaching powder.

After removing outer clothing, each individual should attempt to remove any liquid mustard gas from the skin by one of the following methods:

1. Thoroughly rubbing in, for one minute, either bleach ointment (ointment, antigas No. 1) or aqueous bleach paste over the affected area. This procedure chemically neutralizes the mustard gas.

2. Using ointment, antigas No. 2 (composed of chloramine-T in a vanishing cream base). It is used like ointment, antigas No. 1, but need not be wiped off.

3. Repeated swabbing of the contaminated area with kerosene, gasoline, or other solvent of liquid mustard gas. These do not destroy the gas but merely dissolve it; swabbing must be confined strictly to the contaminated area and must be repeated. Oilskin or rubber gloves must be used, or the swab should be only partly moistened with the solvent and should be held between the finger and the thumb by the dry portion, care being taken that none of the solvent runs over the skin. The process should be repeated for several minutes with fresh swabs or as long as the characteristic odor of the gas persists on the skin. Thorough washing with soap and water will complete the treatment.

4. Scrubbing with soap and water, using hard soap and frequent changes of water. This again merely removes the liquid in the lather; the scrubbing should, therefore, be confined to the contaminated area and the hands should be safeguarded, if possible, by suitable gloves.

If the liquid contamination is localized and of known saturation, this procedure is effective if carried out promptly. Vesication of the skin is usually prevented if the treatment is

Special Article

Through the courtesy of the Metropolitan Life Insurance Company it is possible for the JOURNAL to publish this Memorandum by Dr. McConnell for the information and handy reference of our members. The material herein is not altogether new, but its particular value in our opinion is that it is gathered together in one place from various sources and constitutes a handy text. It is particularly appropriate because there is not, to our knowledge, at present available a similar condensed text for the information of physicians and others who may, due to the hazards of war, have use for it. Every physician will be well advised to study carefully and to keep handy this short text for ready reference in case of need.—Editor

MEMORANDUM ON PROTECTIVE MEASURES AGAINST COMMON IMPLEMENTS OF WARFARE

W. J. McCONNELL, M.D., New York City

CIVILIAN defense measures against air-raid attacks must aim at prevention of panic and of large scale injuries and damage. Complete protection is not possible, but major catastrophe is to some extent preventable by the training of the population in orderly and disciplined behavior.

As far as can be determined, the efficient chemical warfare materials of England, France, Germany, Italy, and the United States are practically the same. The term gas in connection with warfare is loosely used but includes any chemical substance, solid, liquid, or gas, employed for its poisonous or irritant effect on the human body. War gases are classified generally according to their predominating effects, as: (1) lung irritants—phosgene, chlorine, chloropicrin; (2) vesicants or blister gases—mustard gas, lewisite; (3) sensory irritants (sneeze gases)—diphenylchlorarsine, diphenylcyanoarsine; (4) lachrymators (tear gases)—chloracetophenone, bromobenzyl cyanide, xylol bromide, bromoacetone; (5) direct poisons of the nervous system—hydrocyanic acid gas; (6) gases interfering with the respiratory function of the blood—carbon monoxide, arsine.

Gases may also be classified by their physical properties—especially by their vapor tension and their ability to remain in toxic amounts in any location subjected to their action—as persistent and nonpersistent. Phosgene and chlorine are examples of nonpersistent gases because they disperse in the air and are carried by the air currents. When the contaminated air becomes diluted or is carried away by the wind, the area is immediately habitable. Examples of persistent gases are

mustard and lewisite. Mustard gas is a liquid material that evaporates slowly and will persist for days or weeks in an area and on objects with which persons come into direct contact, thereby making the area uninhabitable unless decontamination procedures are effected. The other gases vary as to persistence. Generally, they are somewhat more persistent than the lung irritants but much less so than the vesicants. It should be kept in mind that gas attacks may consist of two or more types of gas and that while one may soon cease to be present in dangerous concentrations the other may persist for varying periods of time.

Our Chemical Warfare Service has expressed the opinion that "no agent is known which is more effective than mustard gas in sending victims to the hospital, and there is little evidence that a gas more effective than phosgene is available for poisoning the air."

So far, the implements to which civilians have been exposed the most in the present European war are high explosive and incendiary bombs. Gas bombs, high explosive bombs, or incendiary bombs might be used alone or might be used together. For example, mustard gas bombs may be used with high explosive and incendiaries in order to make rescue and fires more difficult to deal with or decontamination more difficult to carry on. Important among the hazards resulting from bombing are disruption of essential commodity and community services such as water, gas, electricity, and food supplies. Other influences are the loss of sleep, fatigue, noise, exposure to cold, sanitation, crowding, and contagious diseases.

Masks for protection of civilians are not difficult to make, since these are similar to

Assistant medical director, Industrial Hygiene Laboratory, Metropolitan Life Insurance Company.

pharynx may be used when mustard gas is inhaled. Steam inhalations are indicated for the resulting laryngitis and bronchitis. Bronchopneumonia is treated in the usual manner. Warm draughts of weak bicarbonate or other alkaline solution are indicated for alimentary tract.

It should be remembered that severe poisoning may result from ingestion of food and water that have been contaminated. Contaminated food must be destroyed.

Lewisite.—Lewisite produces lesions similar to those of mustard gas. Lewisite is an arsenical compound, and extensive burns caused by it may give rise to symptoms of arsenical poisoning. Its presence is appreciated at once, and the characteristic geranium smell is always found so a respirator may be used immediately. It is readily destroyed by chloride of lime and alkalis. The early treatment outlined for mustard gas is equally effective for lewisite burns. An effective aftertreatment is the application of a thick paste of ferric hydrate in glycerin. In cases where considerable quantities of lewisite are ingested, the additional use of ferric hydrate internally for its antidotal effect against arsenic has been recommended.

Lung Irritants

These gases exert their effects on the lung tissue, hence the necessity of immediate arrest of breathing, application of gas masks and, if possible, prompt retreat from the gassed area.

Essentially the same type of pathologic effect is caused by all lung irritants, the rate of onset and the degree of edema of the lungs being dependent on the particular gas and on its concentration and duration of exposure. The insidious nature of these gases makes it necessary to consider any gassed patient as in a serious condition. Complete rest for at least twenty-four hours should be insisted upon even though the patient feels recovered. Artificial respiration must not be given, since a gassed patient must be kept at absolute rest. Pulmonary edema is the most serious symptom to combat.

Phosgene.—Phosgene is representative of this group. Since it disperses rapidly, it is usually encountered in moderate or low concentrations. The chief advantage of phosgene and chlorine gas is military, since these gases corrode the metals of guns and equipment. However, they are extremely toxic to personnel if inhaled. After exposure to moderate concentrations, a person may feel

able to continue work for an hour or two with only minor symptoms, but he may then suddenly pass into extreme cyanosis (the blue type of asphyxia) and then into the gray stage of collapse (the so-called shock form or pallid type) and die within a few hours. The important acute changes caused by phosgene are practically limited to the lungs.

The essential difference is found in the amount of carbon dioxide in the blood. In blue cases the carbon dioxide is increased and the patient shows marked cyanosis with distention of the superficial veins. The gray cases have an abnormally low carbon dioxide content and present ashen facies, shallow accelerated respiration, and the rapid weak pulse of collapse.

Chlorine and Chloropicrin.—Chlorine is about one-tenth, and chloropicrin about one-half, as toxic as phosgene. They are, however, more irritating to the eyes and upper part of the respiratory tract. In acute poisoning the immediate effect is the production of lachrymation, violent coughing, intense sensation of suffocation, and pain throughout the air passages.

Treatment.—In acute cases rest, warmth, venesection, and oxygen are indicated. Every effort should be made to reduce the oxygen requirement by keeping the patient lying down. The possibility of sudden death and of aggravating pulmonary edema that has begun to subside should be remembered. Warmth will not only combat shock but will diminish any tendency to the muscular movements of shivering.

The important first-aid medical treatment consists of liberal oxygen inhalation. Victims should be transported in stretchers and provided with oxygen inhalation during transportation.

An early subcutaneous injection of 4 mg. of emetine hydrochloride or a dose of from 0.05 to 2 Gm. of ipecac in warm water, unless the victim's heart is weak or there is hypotension, has been recommended.

Venesection should be performed as early as possible in those cases developing pulmonary edema, for it helps to control the edema and at the same time relieves the distention of the right side of the heart. It should be remembered, however, that bleeding is *not* indicated in cases that have reached the gray stage of anoxemia. It may even aggravate the symptoms. Oxygen is always indicated in poisoning by lung irritants. If oxygen can be supplied, the patient's chance of recovery is greatly enhanced. Oxygen should be con-

not delayed beyond five minutes, though an erythema will probably result.

With gross contamination or after contamination with the vapor, the individual should pass through to the undressing room where all underclothing is removed and placed in suitable bins, after which the victim passes on into the cleansing room. To prevent spread of contamination between the undressing and cleansing rooms, an air lock or a room kept constantly decontaminated should be provided, and no person should pass to the cleansing room until completely undressed.

In the cleansing room, cases should bathe in bleach paste or solution, rubbing it well into the skin and then washing off the paste under a shower, care being taken to prevent the bleach from entering the eyes. If it does get into the eyes, it is removed by a cold-water eye douche.

After washing and drying themselves, all persons pass into the dressing room where they must reclothe themselves with clean clothing issued to them.

The clothing can be handled by giving each contaminated person a package of identification tags having a serial number. He places one of these tags on each article of clothing and equipment that he removes and leaves. When he leaves he signs a memorandum receipt for the clothes loaned to him and receives a receipt bearing the serial number of his identification tags for personal clothing and equipment he leaves behind. This receipt may inform him where and when to call for his personal property after it has been decontaminated. At that time he returns clothing that has been issued to him.

The building or section of building used as a gas-cleansing center should be splinterproof and gasproof and should be provided with suitable gastight air locks at its entrance and exit. The interior walls and floors of the cleansing area should be made of nonabsorbent material, such as finished concrete and glazed tile, which does not readily absorb vesicant gas and is easily decontaminated. The floor should have a drain for rapidly draining off contaminated water. Tables and chairs should be covered with oilcloth or other nonabsorbent material. Notices should be posted giving instructions at each stage of the process to prevent confusion.

It should be remembered that the physician and attendants in these areas should be protected against breathing the chemical agent and, in addition, protection should be given to the skin surfaces. The gas mask will protect

only against breathing the poison gas. Special oilskin gloves and oilskin clothing are needed. If possible, extra personnel should be in the area to take care of decontamination so that the physician, attendant, and patient need not be disturbed.

Materials Used

Bleaching powder is ordinary chloride of lime. The English recommend a "supertropical" bleach that is an ordinary bleaching powder stabilized by the addition of quicklime and fulfilling certain conditions of stability and chlorine content.

Bleach ointment (ointment, antigas No. 1) is made by mixing equal parts, by weight, of supertropical bleaching powder (bleaching powder, 30 per cent) and white petroleum jelly.

Aqueous bleach paste consists of supertropical bleaching powder mixed to a creamy consistency with water—roughly, one part of the powder to one or two parts of water by volume. The ointment keeps well, while the aqueous paste retains its effectiveness for several weeks if it is stored in enameled containers with well-fitting lids.

Ordinary bleaching powder is more irritating to the skin than the supertropical, but in the absence of the latter it is quite suitable for preventive treatment, provided it is not kept too long.

Ointment, antigas No. 2 is composed of chloramine-T in a vanishing cream base and is used like No. 1.

A saturated solution of sodium bicarbonate, applied freely and repeatedly, was commonly used during the last war, as was also Dakin's solution or aqueous solution of chloride of lime. These may be used in the absence of bleach powder.

Kerosene is probably the best solvent for the removal of mustard gas from the skin. Its disadvantage is the time required—namely, about thirty minutes. In its absence gasoline or alcohol may be used. The parts must always be thoroughly washed with soap and water after using these solvents.

A 2 per cent solution of sodium bicarbonate should be used to flush the eyes in case mustard vapor irritates them. Under no circumstances should they be bandaged. The nasal and pharyngeal mucous membrane should be irrigated with similar bicarbonate solution. Oil drops (codliver oil) following irrigation are recommended.

Further treatment is similar to the treatment of burns. Bland irrigation of nares and

ADVANCED FIRST AID

Dr. Condict W. Cutler, Jr., chief of the Emergency Medical Service, Manhattan, in co-operation with the Medical Society of the County of New York and The New York Academy of Medicine, arranged for this series of lectures recently given at the Academy—Editor

EMERGENCY CARE OF WOUNDS, HEMORRHAGE, AND SHOCK

L. M. THOMPSON, M.D., Washington, D. C.

ANY consideration of the first-aid care of wounds, hemorrhage, and shock by a physician in preparation for his presentation of the subject to laymen and women who wish instruction in first aid must start with the assumption that "admitting room first aid" and "roadside first aid" are entirely different things. First aid as most of us have been thinking of it and as we have practiced it in our offices or our hospitals with plenty of glass jars full of sterile gauze and sterile solutions, and with nurses standing about with gloves ready for us to slip on our clean hands—these things do not exist when a house crumples in a cloud of dust or when a car turns over on the highway. The layman must be taught how to handle all sorts of wounds with limited material, to keep his hands off in some cases, and to prevent fatal hemorrhage with his hands in other cases. In fact, it may almost be said that a layman must render first aid with his head and his hands and with those things he may get his hands on in the particular situation of each emergency. How then shall we go about teaching him these things?

You have already been told, I assume, that the control of hemorrhage, rendering artificial respiration, and the elimination of poisons take precedence over everything else in first aid.

In severe bleeding we must think first of pressure. With our hands we can usually control all severe bleeding almost instantly if we know the proper pressure points. This not only prevents the further loss of valuable blood and reduces shock, but it has an astonishing effect on the helpless bystanders. It gives you time to think what to do next. If you can step in and instantly put your fingers on the correct spot and stop that spurt of blood, then "the marines have landed and the situation is under control."

Where are these pressure points that work such miracles? There are six of them, located at spots where, by pressure with our fingers, we can compress the artery against a bone behind it and so shut off the blood to the head, neck, and extremities.

1. In front of the ear, for bleeding from the scalp and above the eyebrow.

2. At the side of the jaw, for bleeding of the face below the eyebrow.

3. At the side of the neck, for wounds of the neck and throat.

4. On the first rib behind the inner end of the collarbone, for bleeding of the shoulder and armpit.

5. Inside the upper arm, for bleeding of the arm below that point.

6. In the middle of the groin, for bleeding of the leg.

A tourniquet is rarely needed and in most cases should only be considered as an extra hand to apply pressure. Tourniquets must be released every 15 minutes to permit blood to circulate and prevent death of the part by gangrene.

We have no time to teach the layman the bacteriology of wound contamination and infection. But he knows the danger. He has probably seen an infected wound, and he knows what pus looks like. He wants to prevent contamination turning into infection. His lifelong habit has been to put something on that wound, either an antiseptic or something that grandfather said was good for cuts, and so the layman may have in mind a bread-and-milk poultice, turpentine, chewing tobacco, or something worse, depending on what part of the world grandfather came from.

So we have to teach him what to do for wounds, whether they are abrasions, incisions, lacerations, or punctures. In normal times, in a city of this size with plenty of hospitals and ambulances, we do not worry much about the larger injuries—those that are serious enough so that there is no doubt they will go

Assistant National Director, First Aid Service, American Red Cross.

tinued with only short rest periods until the symptoms of pulmonary edema have subsided and should be given intermittently for from twelve to twenty-four hours thereafter.

Further treatment should be carried on in hospitals where certain drug therapy may be indicated. The administration of 25 per cent gum-glucose solution and possibly urease solution, intravenously, has been found effective.

The first-aid treatment of the irritating effect on the eyes, nose, and throat consists of irrigating with a 2 per cent solution of bicarbonate of soda.

Sensory Irritants

The symptoms from exposure to this group of gases are immediate in onset and are quite characteristic; small quantities in the air cause burning pain in the eyes, nose, and throat, repeated sneezing, lachrymation, nausea, and sometimes vomiting. These symptoms pass away in from thirty minutes to two hours after pure air is reached. Since no organic lesions are produced, treatment, other than wearing the mask, consists in getting out of the atmosphere containing the gas. These gases are used chiefly for their harassing effect and to interfere with the use of the gas mask when used in combination with lung irritants. Generous lavage of the eyes, throat, and nose with a warm solution of from 1 to 2 per cent boric acid or sodium bicarbonate may be used in the aftertreatment of cases.

Lachrymators (Tear Gas).—These have an action similar to the sensory irritants but have a more severe effect upon the eyes. The mask, if properly applied, gives complete protection. Treatment consists of getting out of the gas atmosphere and irrigating the eyes with a saturated solution of boric acid, normal saline, or 2 per cent bicarbonate solution.

Hydrocyanic Acid.—This acid was tried in the last war but was soon discontinued because of the impossibility of obtaining lethal con-

centrations. Because of its extreme toxicity, its further development and use should be considered as a possibility.

Carbon Monoxide.—Carbon monoxide has never been used, but is frequently encountered, as an incident of warfare, since all explosives produce enormous quantities of this gas.

First aid in the case of exposure to these gases consists of exposure to the open air. If respiration is stopped, artificial respiration is indicated. After respiration is started, the inhalation of oxygen or oxygen in combination with carbon dioxide is the best remedy.

Arsine.—Although this gas has not been used, it is possible that it might be developed as a war gas because of the fact that it is heavier than air. It is somewhat unstable but is extremely toxic in fairly low concentrations. It is a hemolytic poison. Symptoms of poisoning usually appear a few hours after exposure to the gas and are manifested by faintness, giddiness, headache, weakness, pain in the abdomen, nausea, and vomiting. The toxic effect on the red blood cells is sometimes intense and severe anemia supervenes. The gas mask protects against arsine for short periods.

Treatment.—Treatment consists in removing the victim from the poisonous atmosphere and administering oxygen. Blood transfusions may be necessary to counteract the anemia. An ample supply of fluids should be given.

Where concealing smokes are employed, phosphorus burns may be encountered. Phosphorus adheres to the flesh or is buried in the subcutaneous tissue and continues to fume, occasionally bursting into flame again after being extinguished.

Treatment.—Protection from all air by means of water or oil is indicated. A 1 per cent solution of copper sulfate to form insoluble salts can also be used. The copper-coated phosphorus may then be removed by forceps or irrigation, and the burn may be treated like any other burn.

THE AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

... and the American Industrial Hygiene Association will hold their joint Annual Convention in Cincinnati from April 13 to 17. The central purpose of the meeting will be to provide a five-day institute for the interchange and dissemination of information on new problems, as well as for the consideration of up-to-date meth-

ods of dealing with those that are well known. The industrial physicians have taken responsibility for the program of the first two and one-half days and the hygienists for the remainder of the five days, but most of the subjects chosen will be of interest not only to physicians but equally so to industrial engineers and executives.

EMERGENCY CARE OF WOUNDS, HEMORRHAGE, AND SHOCK

L. M. THOMPSON, M.D., Washington, D. C.

ANY consideration of the first-aid care of wounds, hemorrhage, and shock by a physician in preparation for his presentation of the subject to laymen and women who wish instruction in first aid must start with the assumption that "admitting room first aid" and "roadside first aid" are entirely different things. First aid as most of us have been thinking of it and as we have practiced it in our offices or our hospitals with plenty of glass jars full of sterile gauze and sterile solutions, and with nurses standing about with gloves ready for us to slip on our clean hands—these things do not exist when a house crumples in a cloud of dust or when a car turns over on the highway. The layman must be taught how to handle all sorts of wounds with limited material, to keep his hands off in some cases, and to prevent fatal hemorrhage with his hands in other cases. In fact, it may almost be said that a layman must render first aid with his head and his hands and with those things he may get his hands on in the particular situation of each emergency. How then shall we go about teaching him these things?

You have already been told, I assume, that the control of hemorrhage, rendering artificial respiration, and the elimination of poisons take precedence over everything else in first aid.

In severe bleeding we must think first of pressure. With our hands we can usually control all severe bleeding almost instantly if we know the proper pressure points. This not only prevents the further loss of valuable blood and reduces shock, but it has an astonishing effect on the helpless bystanders. It gives you time to think what to do next. If you can step in and instantly put your fingers on the correct spot and stop that spurt of blood, then "the marines have landed and the situation is under control."

Where are these pressure points that work such miracles? There are six of them, located at spots where, by pressure with our fingers, we can compress the artery against a bone behind it and so shut off the blood to the head, neck, and extremities. .

1. In front of the ear, for bleeding from the scalp and above the eyebrow.
2. At the side of the jaw, for bleeding of the face below the eyebrow.
3. At the side of the neck, for wounds of the neck and throat.
4. On the first rib behind the inner end of the collarbone, for bleeding of the shoulder and armpit.
5. Inside the upper arm, for bleeding of the arm below that point.
6. In the middle of the groin, for bleeding of the leg.

A tourniquet is rarely needed and in most cases should only be considered as an extra hand to apply pressure. Tourniquets must be released every 15 minutes to permit blood to circulate and prevent death of the part by gangrene.

We have no time to teach the layman the bacteriology of wound contamination and infection. But he knows the danger. He has probably seen an infected wound, and he knows what pus looks like. He wants to prevent contamination turning into infection. His lifelong habit has been to put something on that wound, either an antiseptic or something that grandfather said was good for cuts, and so the layman may have in mind a bread-and-milk poultice, turpentine, chewing tobacco, or something worse, depending on what part of the world grandfather came from.

So we have to teach him what to do for wounds, whether they are abrasions, incisions, lacerations, or punctures. In normal times, in a city of this size with plenty of hospitals and ambulances, we do not worry much about the larger injuries—those that are serious enough so that there is no doubt they will go

Assistant National Director, First Aid Service, American Red Cross.

to a doctor or hospital. All we need to do is to protect them from further contamination, further injury, and shock. Probably the best thing we can do for them is to cover the wound with sterile gauze or the cleanest household linen available, try to prevent shock, and let the doctor do the rest.

But the wounds we worry about are the little wounds—the cuts, scratches, blisters, and splinters, so small that even though we tell the owner to go to see a doctor we know he will not do so. He doesn't think it necessary or he just hasn't the price. In an air raid he wants to find his family and salvage his valuables, or he may be unable to find a doctor for days even if he tries. These are the wounds that may give us the fatal infections, and these wounds should have the protection of mild tincture of iodine, especially on the surrounding skin. Allow the iodine to dry and apply a sterile dressing.

Even these minor wounds should, of course, be seen by a physician—no layman will do a second dressing. That is outside the field of first aid and is the sole responsibility of you doctors.

The use of the sulfonamide group of drugs is raising much attention at the present time. Since, however, their use is still under debate by the physicians, we do not feel that it is yet safe to put these strong drugs in the hands of laymen, and they should be used only under the supervision of a physician.

All wounds causing severe pain or hemorrhage will be accompanied by shock. In the field or along the roadside we cannot use the methods for shock prevention and treatment that you know in the hospital. Laymen do not understand hemoconcentration. They have never seen a shock bed. We can teach them, however, the fundamental principles of heat, position, and stimulants.

Heat may be applied with plenty of blankets, robes, or coats beneath, as well as above, the injured person. Artificial heat may be

given by the use of hot-water bottles, which must be improvised by the use of fruit jars or any empty bottles filled with hot water. Remember that automobile radiators are full of hot water and may be your only source of water for filling bottles on the roadside.

Elevate the feet and keep the head low. This may be done by the natural slope of the ground or by placing the feet on boxes, automobile seats and similar objects. If a stretcher or cot is available, raise the foot end 18 inches if necessary.

After the bleeding has been controlled, stimulants may be given such as sweetened hot tea or coffee. Remember that alcohol lowers the temperature by increased radiation and acts as an ultimate depressant and is not a good first-aid stimulant.

During transportation we must continue the shock treatment. Therefore, do not put these people in a car in a sitting position but keep them lying down and drive carefully to avoid additional accidents.

First aid, in order to be effective, must be given as promptly as possible after the accident. There is not time for trained medical units to arrive from a distance. The people at the site of the accident must know how to give first aid. Otherwise, they will probably do the wrong thing in an effort to help.

Therefore, the American Red Cross is training literally millions of people in the fundamental skills of first aid, including the control of bleeding, the immobilization of fractures with traction splints, artificial respiration for those who have stopped breathing, the care of burns, and the proper transportation of the injured.

You, as physicians, will be called upon to help instruct these classes. The public expects you to know these fundamental skills and to be able to present them so that laymen may understand and remember what to do and what not to do. Only with your assistance can we meet the present emergency.

EMERGENCY CARE AND TRANSPORTATION OF FRACTURE

ROBERT H. KENNEDY, M.D., New York City

WE ARE at war. There are three major reasons why every medical graduate should obtain instruction in first-aid care at this time. It is immaterial whether he is liable to be called into the armed forces or not.

Until recently, first-aid procedures were not taught in medical schools or hospitals. Even at the outbreak of war only a small percentage of medical schools gave any instruction in first aid. You and I know nothing about it except as we have been trained through the American Red Cross, the Boy Scouts, or the Girl Scouts. The Red Cross has issued over three million certificates to laymen after they completed their course and passed an examination in first aid. Many doctors have objected to laymen receiving this training. This is largely because they know nothing about what is taught and have not been sufficiently interested to investigate. Now we may need a great bulk of first aid applied by laymen, and it is important that we gain knowledge of and promote such training rather than decry it.

Second, many doctors are being called upon to teach first-aid classes. They have neither the background of first-aid knowledge nor the training in the proper approach to instructing a layman. Yet the Red Cross has a ruling that any doctor holding a license to practice in his state is to be given an instructor's rating on application. Before starting a class, each doctor should purchase an *American Red Cross First-Aid Textbook*⁴ from his local chapter and follow it in detail in his instruction. The book has gone through frequent editions for more than thirty years, with changes made according to the advice of progressive members of the profession. Not one of us would agree with everything in it any more than we would with any medical book we have ever used. But basically it is sound. Only by having everyone trained in the same manner can there be teamwork when disaster comes.

Third, any of us may be called upon to render first aid under civilian defense in our own home, apartment house, or in a casualty station. We must be ready to do justice to the victims.

Further, this training is of equal value in peace-time casualties which will always be with us. Remember that during all the

months of active bombing in England, there were more victims each month from motor-car accidents than there were from bombing raids.

The general principles² in the emergency care of all fractures are:

1. Combat any shock.
2. If suspicious that a fracture is present, render care as a fracture.
3. Avoid all unnecessary handling.
4. Protect any existing wound by the best means available.
5. Splint effectively, wherever found, before transporting.
6. Transport carefully.

The saving of life comes first; the saving of limb, second. If the patient is in shock, this demands treatment before anything is done for the injured limb. There is no use in splinting a limb carefully, while neglecting to treat shock from which the patient may be dying. On the other hand, traction on an extremity may be an effective means of combating shock. Morphine is the first and best treatment for shock. Sufficient morphine should be given to relieve pain and thereby relieve the patient's restlessness. The body heat must be maintained by sufficient extra covering and the use of external heat.

Bleeding should be stopped. It is rare that this cannot be done with a firm compression bandage. Tourniquets should not be used until compression of the wound has proved of no avail. Deaths from hemorrhage have been caused by an improperly applied tourniquet which allowed some arterial blood to enter the part and only shut off the venous return. It is common to see all bleeding stop as soon as a tourniquet is removed. If a tourniquet must be used, it should be loosened every half hour to allow blood to return to the part distal to the tourniquet. If a tourniquet is applied too tightly or for too long a period, gangrene, paralysis from nerve pressure, or lowered resistance to infection may result.

The patient should not be picked up hastily and dumped into the first automobile and rushed to a doctor's office or hospital. It is far better to cover him adequately and let him lie on the ground where he was found until splints can be put on and then move him in an ambulance. If it is necessary to change his position at all before splinting—in the

instance of an extremity fracture—continuous pull should be exerted by the hand on the injured part while he is being moved.

Fractures of the long bones of the extremities and of the spine exceed all other severe injuries in frequency and in the possibility of better results by proper emergency care and correct transportation. In major fractures the initial care given at the place of accident and the method of transportation influence the ultimate good or poor result. Death, permanent disability, loss of earning power, and dependence on the community may be the price of lack of attention to the necessary details of what should be done at this critical time. At the instant a long bone is broken, nature tries to protect the part from more injury. If there is any displacement, the muscles shorten and the fragments ride by one another, resulting in the only possible natural splinting. Such splinting is fairly effective while the part is at rest, but it does not offer sufficient protection when the patient is moved.

In any injury sufficient to break a bone, soft tissue damage is always present—muscles; blood vessels, small or large; even nerves or skin. This soft tissue damage is often more important than the fracture itself. Except in fractures by direct violence, such as an automobile wheel passing over a leg, the soft tissue damage results chiefly from the movement of displaced bone fragments. This movement is often slight at the moment of accident. But *beware* of the damage that occurs in trying to be helpful. Should the injured person be assisted to his feet or should an attempt be made to carry him even a few feet, the ends of the broken bone may be pulled by one another by muscular contraction, which results in overriding. As a result, the soft part damage is often made much more severe than in the original injury, since the bones churn about in muscle and other tissues. This increases shock and hemorrhage as well as the pain suffered by the injured, since these are based much more on soft part than on bony injury.

There is only one way to prevent this: Pull on the extremity sufficient to overcome the muscle pull on the broken strut. This pull is called "traction" and may be exerted perfectly well by hand. However, it is impossible to maintain a steady hand pull for any great distance or length of time. The amount of traction becomes irregular or jerky, causing more damage and shock each time it changes. To overcome this, splints were developed at

least seventy years ago by which a steady amount of traction could be exerted for as long as necessary. These are known as "traction-fixation splints." They were improved greatly during the War of 1914 to 1918, resulting in the Keller-Blake hinged halting ring splint for the lower extremity and the Murray-Jones hinged arm splint for the upper extremity. These are ideal when they can be obtained and applied before the injured person is moved at all. Efforts should be made to see that they are available wherever injuries are liable to occur. When these are not obtainable, excellent improvised methods of traction-fixation have been devised using materials at hand, such as forked sticks, brooms, mops, and ski poles, with triangular bandages, rope, etc., for exerting traction. A long side splint to the body and thigh never kept the fragments of the shaft of the femur from moving about and doing more damage to the soft parts, which increased shock and hemorrhage. Hand traction is much preferred to the long side splint, and traction-fixation is more effective than hand traction.

There are three types¹ of compound fractures. If a wound is present and there is no way of knowing whether the bone has been soiled, traction will protect the bone from coming out through the wound or spreading contamination in the soft parts by movement of the fragments. If the compound fracture has been produced by a possibly soiled object penetrating the extremity, traction will prevent the contamination from being spread farther in the soft parts. These are the two common types of compound fractures. Much more rarely, the end of the bone projects through the skin and gets dirty. The application of traction may draw this soiled bone back under the skin. These are extremely serious cases with regard to both life and limb. They all need to be operated on if they can possibly reach an operating room within six hours. This can usually be done in the United States. Application of traction-fixation is probably advisable. In such cases a message to the hospital should accompany the injured person explaining that the bone has projected. If it is practically certain that the injured cannot reach a properly equipped operating room in six hours, there is a question whether more contamination will occur from the bone disappearing under the skin with traction or from the churning about of the other fragment remaining under the skin without traction.

From the standpoint of the greatest good to

the greatest number, more harm is done by the omission of traction in the first two groups than is done by its application, with theoretic objections, in the third group. Light traction is never to be advised. There must be sufficient traction to overcome the pull of the muscles in all instances to be of any value.

"Splint 'em where they lie and splint 'em effectively."

In the lower extremity traction splints should be used for a possible fracture anywhere from hip joint to ankle joint and for large wounds involving muscle. The half ring rests against the tuber ischii as the upper point of traction-fixation and the foot is tied to the lower end of the splint as the lower point. In the upper extremity the splints are of advantage anywhere between the shoulder joint and the lower third of the forearm.

There are six requirements for the proper application of traction splints to the extremities.

1. There must be some adequate form of hitch, and it is necessary to protect the part beneath the hitch so that it will not be injured.

2. A traction hitch should be applied above the ankle or wrist.

3. There must be some means of increasing the traction so that the desired pull is obtained.

4. The extremity being in traction, it must be supported from below.

5. Lateral movement must be prevented.

6. The whole splint must be suspended in such manner that the heel will never be pressed upon.

It takes no more than one-half to one hour to learn to apply both the ready-made and the improvised splints. If the materials are at hand, the ready-made splints can be applied in three minutes. Any extra time required for the application of the improvised splints is only that needed to get the materials together. The simplicity of applying improvised splints under the most adverse circumstances makes lack of knowledge of this procedure inexcusable. Facility in application can be acquired only by practice, and its efficacy can be best appreciated by having splints applied to oneself.

In the event of air raids, we have no idea that these splints will be applied in a blazing building or when the walls are collapsing. But even air-raid wardens should know their value and the necessity of their application before any moving of a victim, unless he is in a position of the gravest immediate danger. Speed in reaching the first-

aid post or hospital before being properly splinted is a complete misconception.

Injuries to the spine form another group in which the knowledge of emergency care and transportation is of tremendous importance. While not as frequent as fractures of the long bones of the extremities, there are probably more instances of death and permanent disability as a result of the manner in which the victim was handled between the moment of injury and his arrival at a hospital. Many injured persons with broken spines had no paralysis before someone attempted to move them.

If the mechanism of injury is such that a fracture of the spine might have been produced, transport as a fracture, even though no objective signs are made out on examination. If a fracture of the spine might be present and the victim is unconscious, handle him as though his neck were broken.

If a patient³ complains of pain in his back, he may have a broken back. If he complains of pain in his neck, he may have broken his neck. Never lift an injured person or his head until he has told you whether he can move his legs or fingers. If he cannot move his legs, his back may be broken. If he cannot move his fingers, his neck may be broken. In both cases the spinal cord is injured. If you lift his head to give him a drink of water or if you fold him up to carry him, you may grind the injured spinal cord between parts of the broken spine and destroy any useful remnant of the spinal cord which may have escaped injury in the accident. Do not assist or allow the victim to sit up.

This same advice is fully as important when no evidence of cord injury is found but when, from the mechanism of injury, a fracture might be present. In one instance we have evidence of cord injury present, possibly permanent, and are trying to save anything which remains. In the other, we have no evidence of cord damage. How much more important it is to preserve that person from suffering any degree of permanent paralysis as a result of the method of moving, however well intentioned.

In fractures of the dorsal or lumbar spine the usual injury is a crushing of the body of the vertebra in flexion. The principle of hyperextension should therefore be carried out in transportation. Any of the ordinary lifts usually flex the spine and are to be avoided. When lying on one's back the lumbar curve is decreased; i.e., the tendency is toward flexion of the spine. Therefore, such an in-

instance of an extremity fracture—continuous pull should be exerted by the hand on the injured part while he is being moved.

Fractures of the long bones of the extremities and of the spine exceed all other severe injuries in frequency and in the possibility of better results by proper emergency care and correct transportation. In major fractures the initial care given at the place of accident and the method of transportation influence the ultimate good or poor result. Death, permanent disability, loss of earning power, and dependence on the community may be the price of lack of attention to the necessary details of what should be done at this critical time. At the instant a long bone is broken, nature tries to protect the part from more injury. If there is any displacement, the muscles shorten and the fragments ride by one another, resulting in the only possible natural splinting. Such splinting is fairly effective while the part is at rest, but it does not offer sufficient protection when the patient is moved.

In any injury sufficient to break a bone, soft tissue damage is always present—muscles; blood vessels, small or large; even nerves or skin. This soft tissue damage is often more important than the fracture itself. Except in fractures by direct violence, such as an automobile wheel passing over a leg, the soft tissue damage results chiefly from the movement of displaced bone fragments. This movement is often slight at the moment of accident. But *beware* of the damage that occurs in trying to be helpful. Should the injured person be assisted to his feet or should an attempt be made to carry him even a few feet, the ends of the broken bone may be pulled by one another by muscular contraction, which results in overriding. As a result, the soft part damage is often made much more severe than in the original injury, since the bones churn about in muscle and other tissues. This increases shock and hemorrhage as well as the pain suffered by the injured, since these are based much more on soft part than on bony injury.

There is only one way to prevent this: Pull on the extremity sufficient to overcome the muscle pull on the broken strut. This pull is called "traction" and may be exerted perfectly well by hand. However, it is impossible to maintain a steady hand pull for any great distance or length of time. The amount of traction becomes irregular or jerky, causing more damage and shock each time it changes. To overcome this, splints were developed at

least seventy years ago by which a steady amount of traction could be exerted for as long as necessary. These are known as "traction-fixation splints." They were improved greatly during the War of 1914 to 1918, resulting in the Keller-Blake hinged half ring splint for the lower extremity and the Murray-Jones hinged arm splint for the upper extremity. These are ideal when they can be obtained and applied before the injured person is moved at all. Efforts should be made to see that they are available wherever injuries are liable to occur. When these are not obtainable, excellent improvised methods of traction-fixation have been devised using materials at hand, such as forked sticks, brooms, mops, and ski poles, with triangular bandages, rope, etc., for exerting traction. A long side splint to the body and thigh never kept the fragments of the shaft of the femur from moving about and doing more damage to the soft parts, which increased shock and hemorrhage. Hand traction is much preferred to the long side splint, and traction-fixation is more effective than hand traction.

There are three types¹ of compound fractures. If a wound is present and there is no way of knowing whether the bone has been soiled, traction will protect the bone from coming out through the wound or spreading contamination in the soft parts by movement of the fragments. If the compound fracture has been produced by a possibly soiled object penetrating the extremity, traction will prevent the contamination from being spread farther in the soft parts. These are the two common types of compound fractures. Much more rarely, the end of the bone projects through the skin and gets dirty. The application of traction may draw this soiled bone back under the skin. These are extremely serious cases with regard to both life and limb. In such cases a message to the hospital should accompany the injured person explaining that the bone has projected. If it is practically certain that the injured cannot reach a properly equipped operating room in six hours, there is a question whether more contamination will occur from the bone disappearing under the skin with traction or from the churning about of the other fragment remaining under the skin without traction.

From the standpoint of the greatest good to

EMERGENCY CARE OF ABDOMINAL INJURIES, HEAD AND CHEST INJURIES, AND BURNS

FREDERIC W. BANCROFT, M.D., New York City

THE present war has developed types of injuries which are not seen in civilian life and were rarely seen during the past World War.

I mention two of these conditions because, when seen shortly after injury, they may have no signs of external violence but they must be recognized and hospitalized.

These injuries occur during bombing raids and may affect all ages and both sexes. The injuries are: (1) *concussion or blast injuries* due to high explosive bombs, which create, first, a strong positive pressure wave of air and, second, a negative pressure wave of air; (2) *crush injuries*. Different methods of warfare either bring new problems or revive old problems in new disguise, and the crush injury may fall into either category. It is characterized by acute renal failure occurring in people who have been trapped under falling masonry.

The typical clinical picture is as follows: The patient has been buried for several hours and subjected to pressure. On admission, the general condition appears to be good. There may be no local injury but, when there is, local swelling, edema, and whealing, followed by bullous eruption of the skin and local anesthetic areas, appear. A few hours later, in spite of vasoconstriction as shown by pallor, coldness, and sweating, the blood pressure falls and the hemoglobin concentration rises. Later, the urinary output progressively diminishes and contains albumin and many dark brown casts. The patient is alternately drowsy and anxiously alert to the severity of his condition, and his blood pressure often remains raised. Edema, vomiting, and thirst then set in, the blood urea and potassium become increasingly high, and death in the bad cases generally occurs suddenly, usually about the seventh day. Autopsy shows a necrosis of muscle and degenerative changes in the renal tubules. This micro-pathology resembles that found in cases of incompatible blood transfusion, but occurs without transfusion. It is not clear how much lowered blood volume and diminished renal blood flow or catabolic products, produced by dead or dying tissues, have to do with it.

In discussing the subject of first aid in

abdominal injuries, head and chest injuries, and burns, one must, I believe, divide these subjects into, first, patients where evacuation can be immediately performed and, second, cases where it is impossible because of the size of the calamity to transport cases without considerable delay.

In this latter condition the physician on the scene becomes in reality a member of a first-aid casualty station. It is obvious that in the latter classification the physician may have time to do more than render the initial first aid. One may conceive a situation where a large number of injuries occur in a given area and where it is impossible to transport these cases immediately. In this instance the physician must do more than render first aid, and it is imperative that he place on the identification tag of the patient a brief summary of his findings, what preliminary diagnosis he has made, and what first-aid treatment he has given. This must be in addition to the marks on the forehead relative to any inoculation, etc. One may further conceive that when these patients come into an overcrowded hospital the notes made by the physician who rendered first aid will greatly assist an overworked and overrushed hospital crew. From his notes may be determined whether the patient should be immediately rushed to the operating room or whether it is safe to delay until the more desperately wounded are cared for.

In attempting to discuss first aid, therefore, I shall concentrate largely on this second group of cases, because you have been given full information on the initial treatment of shock and hemorrhage in the preceding article by Dr. Thompson.

Abdominal Injuries

Abdominal wounds may be, first, crushing injuries where there is no external break into the abdominal cavity—in this group come injuries to the solid organs and to the gastrointestinal tract; second, penetrating wounds, which may have either large or small perforations due to shell fragments; third, eviscerations, where the muscles of the abdominal cavity may have been widely lacerated, with protrusions of the abdominal viscera (such eviscerations may be with or without evident

jured person should not be moved face upward unless some object is placed beneath the lumbar spine to keep it in extension. It is difficult to accomplish this without undue movement of the victim's trunk. Therefore, when the back is broken, place a door, shutter, or other wide board beside the victim and, holding him at the shoulders and hips, roll him slowly and gently so that he rests on his abdomen with his face turned to one side. The trunk must be moved as a unit in turning him. In the face down position any flexion of the spine is practically impossible.

In case a door, etc., is not obtainable and the victim must be moved immediately from a point of danger (or to lift him to the regulation Army stretcher, which is several inches above the ground) the victim may be rolled in the same way onto a blanket, lying prone. This can be lifted or carried by grasping the blanket at the level of the shoulder above and knees or thighs below, producing a slight, but not marked, hyperextension. The victim should be lifted on a rigid support whenever possible.

A blanket lift should not be used in the instance of a possible broken neck. A door, plank, or shutter must be obtained which will extend at least 4 inches beyond the victim's head. It should not be less than 5 feet long and 15 inches wide.

If the victim is on his back, one person should kneel above the victim's head and, holding the head between two hands, steady it so that the head, neck, and shoulders move as a unit with the body without bending. One or more persons may then grasp the victim's clothing at the shoulders and hips and carefully slide the victim sideways onto the board or door, so that he stays *face upward* with arms at sides and *head, trunk, and extremities* on the board. *The head must not be raised or the neck bent forward or sideways.* The arms may then be folded over the chest

and held together by safety pins or bandage. Several straps or bandages should be placed around the victim and the board to hold the victim in place during transportation. No pillow should be placed under the head, but sweaters, clothing, or improvised small sand bags may be placed against the sides of the head to keep it from rolling to the side during transportation. The chin should be up. The board with the victim on it may then be lifted onto a blanket or a stretcher, and carried by two or more bearers.

If the victim with a broken neck is found lying face downward, a door or board should be placed beside him as described above, and the arm on that side extended above the head. The person kneeling at the head must firmly grasp the victim's head at the sides, the hands covering the ear and the angle of the jaw. Then, as the victim is rolled onto the board, his head must be steadied and kept in line with the body as he is turned to the *face up* position. Moderate traction may be exerted with the hands holding the head as the victim is rolled onto the board by one or more assistants kneeling at the side of the board. The head and trunk must be turned in unison. *Under no circumstances must the head be tilted forward or backward.*

The details of all these procedures are well described in the *American Red Cross First-Aid Textbook*. They cannot be appreciated without actual personal practice. Their value to the injured person cannot be overestimated. "Splint 'em where they lie" if you wish to save life and limb.

work upon blast concussion injuries, states as follows:

"In 40 per cent of the experimental animals examined there were hemorrhagic lesions in various abdominal organs; all these cases exhibited pulmonary hemorrhages; also the abdominal organs appear to be less sensitive to blast than the lungs. The organ most frequently damaged by blast in the abdomens of experimental animals is the large intestine; patches of hemorrhage may be found varying from punctate spots under the serous coat to large annular bands of hemorrhage and even rupture. The small bowel is less frequently affected, as is the stomach. The liver may be bruised or torn or the right lateral surface may be diversified by lines corresponding to the ribs. The spleen, kidney, and bladder are less often implicated. Blood clots have been found in the peritoneum, and retroperitoneal hematomas may be found as well.

"The direct effects of blast are experienced only when close to the explosion, but there are many indirect effects which may produce death or serious injury."

Further experimental technical descriptions of blast injuries will be given under the heading "Injuries of the Chest."

In presumed abdominal injuries it is advisable to give nothing by mouth, since one does not know whether or not there may be perforation of a hollow viscus. This dictum should be carried out even with regard to alcohol.

The treatment of nonpenetrating abdominal wounds, if transportation can be readily provided, is simple; morphine for the initial shock is all that is necessary for these cases. If, however, it is obvious that transportation will be delayed, the doctor's initial examination and diagnosis may aid tremendously in the later treatment of this patient when he arrives at the hospital. If space and time permits, the clothing should be freed enough to allow a careful physical examination, care being taken not to increase shock. If there is no external wound, what are we to consider in our diagnosis of abdominal injuries? Beginning at the upper abdomen I shall enumerate the most common injuries and some of the clinical signs that one should be able to determine in a so-called casualty clearing station.

Rupture of the Diaphragm.—This is an often overlooked lesion that occurs from the result of an injury creating an increased abdominal pressure. Gatsch reported 6 cases within two years which he had operated on. In all of

these cases the tear in the diaphragm extended outward and slightly backward from the esophageal hiatus. All of these patients were injured in automobile accidents, and he believes the tear was caused by the sudden great increase in intra-abdominal pressure due to a forward flexion of the body when the diaphragm and muscles of the abdominal wall were too strongly contracted. Unfortunately, the physical signs in these injuries are not well classified, and one could only make a presumptive diagnosis from cyanosis, diminished respiratory action, and splinting of the muscles in the upper part of the abdomen.

Rupture of the Spleen.—Inspection may reveal swelling or absence of respiratory motion in the left upper quadrant. On palpation, tenderness and a sense of fullness can frequently be detected and, on percussion, gastric tympany will be obliterated and a dull note heard in the lower left part of the chest posteriorly and in the axilla. As an aid to diagnosis in splenic injuries, Max Saegesser, of Berne, notes that there is a point of extreme tenderness when finger pressure is made in the supraclavicular area between the sternomastoid and scalenus anticus muscles. In all the injuries seen by him, pressure started up violent pain, as contrasted with the absence of pain on the right side. He believes the cause of this is that sensory branches from the splenic capsule run upward in the left phrenic nerve.

Rupture of the Liver.—Local tenderness below the right costal margin, increased liver dullness, and evidence of hemorrhage are the most common signs.

Rupture of the Stomach.—This is rare and, therefore, cannot often be diagnosed at first aid.

Rupture of the Duodenum.—This is a quite common injury. It occurs in 10 per cent of all the ruptures of the hollow viscus. A rupture of the retroperitoneal portion of the duodenum occurs in 30 to 35 per cent of the above group. In the retroperitoneal ruptures Butler and Carlson have pointed out that pain in the testicle is a symptom due to the irritation of the sympathetic nerves. Some time later, if the rupture is retroperitoneal, crepitation may be felt in the right lumbar muscles.

Perforations of the intestines, either large or small, are created by two types of physical injury—first, crushing of the viscus against the spine, causing a direct rupture and, second, sudden increase in intraluminary pressure created by the trauma, which causes a blow-out perforation as one sees in an automobile

intestinal perforations); and fourth, compression injuries to the bladder and kidney.

One may lay down certain general principles in treating abdominal injuries, such as care in moving a patient. Each transportation of a patient with an injured abdominal viscus increases the danger of shock and hemorrhage. Moving a patient from one room to another, or from one side of a street to another, and then removing him is dangerous. It is up to the physician, therefore, to attempt to use his judgment as to where the patient should be moved from the site of injury until transportation can be provided. Where there are lacerated wounds one must consider that each wound goes through two stages. The first stage is during the first six hours after injury, where there is contamination without much bacterial multiplication, and, second, after six hours, when bacterial multiplication and dissemination takes place. If it is obvious that immediate transportation cannot be done, the use of sulfathiazole, which is provided in the emergency kits from the hospitals, should be instituted as a first-aid dressing. However, as sulfathiazole is limited in all first-aid boxes, one must use keen judgment to apply it only in the necessary cases.

Mr. Broster, of London, England, states that the abdominal injuries in the present war are much less than in the previous war. He states that in this war only 2 per cent were wounded, with a high mortality rate, and he quotes from Rear Admiral Gordon Taylor as follows:

"So far in this present conflict, the abdominal surgery of warfare has seemed conspicuous by its absence rather than its frequency. The paucity of the lesions of the belly produced by enemy action, which are not beyond all surgical aid, must have impressed those observers whose sphere of surgical action in the Franco-British Casualty Clearing Zone twenty-odd years ago furnished them with an abundant experience of operative aid for those soldiers who were suffering from wounds in the abdominal area. In the past twenty months during which the writer has had the fortune to make official contacts with hospitals along a considerable length of our coastline and some of the corresponding hinterland, the numerical disparity between the operations performed for abdominal injuries by one surgeon on the British front in France a quarter of a century ago and the total aggregate attained in this campaign by many operators, mostly working in England, has been impressive.

"The severity and frequency of crush injuries of the trunk, including the abdomen, has been a feature of casualties on the Home Front. Nonpenetrating injuries of the abdomen and its contents played a relatively small part in the abdominal surgery of the last war; this time civilians, women and children of tender years and even the unborn babe, are suffering crush contusions from falling masonry and from burial under collapsed houses and dwellings. Fragments or masses of wood, stone, or metal may be confusedly hurled with devastating force against the abdomen; severe visceral damage or retroperitoneal hemorrhage may be produced by 'blast' without any external evidence of injury. The abdominal parietes may suffer along with the subjacent organs, and effusions of blood may be encountered in any of the layers superficial to the peritoneum. Actual rupture of the abdominal musculature along with visceral injury was infrequent in the last war; the blow that ruptured the powerful abdominal muscles became too spent to damage the intestinal tract. The increase of destructive force nowadays destroys and damages without fine anatomical distinction.

"Multiplicity characterizes the wounds and damage sustained from air bombardment; not only is the mortality raised by lesions of many viscera but many, even most, of the regions of the body may be simultaneously damaged. The bespattered trunk and limbs in those who have been wounded by high explosives were familiar to the surgeons in the last war, but the phenomenon is far more frequent in this conflict, and the severity of the concomitant injuries renders the prognosis of many an abdominal case hopeless.

"Some of those injured in the abdomen may also suffer burns of the body or limbs. This complication of abdominal injuries may be encountered in ships or on shore; the prognosis will obviously become far more grave in such cases.

"The degree of shock encountered among the casualties of this war far transcends that with which surgeons became familiar between 1914 and 1918. Despite the elaborate and highly organized resources of our transfusion services, despite the transfusion of many pints of blood or plasma, despite the administration of oxygen and all the resources of resuscitation therapy many of those wounded in the trunk remain in a condition of shock which precludes all thought of surgical interference."

Broster, in reporting upon the experimental

"(2) *Provision of Adequate Respiratory Airway.*—Loss of bone and muscle attachment frequently results in loss of control of the tongue with danger to respiration. This is best controlled by use of a long suture through the tip of the tongue. It should be long enough to draw the tongue forward and may be attached to the dressing or clothing. If a needle and suture are not available, the tip of the tongue may be transfixed with a large safety pin. A piece of gauze or bandage may be attached to the tongue suture or safety pin for traction to improve and clear the air passage. These considerations are particularly important if the patient is unconscious. In other cases, due to swelling of the soft tissues, sufficient airway can be provided by insertion of a rubber tube through the nose or the mouth to the nasopharynx. If these means are not adequate, tracheal puncture through the skin with a special trocar will usually save the situation. It is expected that these tracheal trocars will be added to the emergency kit. Tracheotomy should be considered only as a last resort, since it is followed by a high mortality in cases of this type.

"(3) *Temporary Approximate Reduction and Fixation of Bone Fragments of the Maxilla.*—Intelligent application of emergency treatment reduces the period of hospitalization and assures far greater success in subsequent treatment with a minimum of deformity. Early treatment should be such as to assure every chance for the restoration of the original occlusion of the teeth or the restoration of the function of mastication, even in those cases with considerable loss of bone. It is particularly important that the collapse of bone segments be avoided. In order to minimize infections, early cleaning of the wound is essential, and tooth fragments, foreign matter, completely detached particles of bone, etc., should be removed. Bone fragments which have attachment of the soft tissues should be allowed to remain, as they frequently keep their vitality and aid in restoring the continuity of bone. Reduction of fragments by manipulation and temporary fixation by simple measures, such as bandages and elastic traction, should be done, if possible, at this time.

"Fractures of the superior maxilla frequently displace the loose structures downward and backward and definitely interfere with respiration. In case of a bilateral comminuted fracture of the posterior part of the mandible, the anterior part of the jaw may

drop backward and likewise cause serious interference with respiration. In a case of this kind, the front of the jaw may be held forward by a simple emergency splint developed at the Walter Reed Hospital and found practical in several cases. The only articles required are three or four wooden tongue depressors, adhesive plaster, a 2-inch bandage, and the ligature wire supplied with the emergency maxillofacial kit. Two tongue depressors are placed end-to-end and fastened by a third overlapping them in the middle with adhesive plaster. This piece is secured in a vertical position with a bandage passed around the head in the frontal region, with the lower end extending in front of the chin. A wire is passed around the lower teeth or around the chin segment of the mandible and the ends of the wire are fastened to the lower end of the tongue depressor piece. The spring of this will effectually draw and keep the anterior segment of the mandible forward. In the case of backward displacement of the upper jaw, forward traction can likewise be made by attachment of the upper front teeth to this apparatus.

"(4) *Provision of Safe Transportation from the Combat Zone to Hospitals in the Rear.*—Transportation or evacuation from the combat zone places a certain responsibility on the medical department units, for casualties must be prepared for safe, unattended travel by ambulance. Aside from problems of sedation and prevention of shock, special considerations apply to face and jaw injuries. Lessons in past wars are convincing proof that ambulant or semiambulant cases with oral or pharyngeal wounds should sit up during evacuation. If he must be recumbent, the patient should be placed face down if there is any danger of obstruction in the air passages. These precautions lessen the mortality rate of jaw injuries during evacuation."

Dr. James Barrett Brown said in discussion of the foregoing article: "To get the jaw forward quickly, I use a fishhook with the barb cut off and stick it under the chin. It is pulled forward quite easily that way."

Chest Injuries

I am indebted to Frank Berry, of New York, for what I shall say on first-aid treatment of wounds of the chest. I should recommend that all of you read his entire article, parts of which I have copied verbatim. This article on "The Treatment of Injuries of the Chest" was published in the *American Journal of Surgery*, October 1, 1941.

ture. Definite localized pain, diminished liver dullness, and signs of peritonitis as evidenced by rigidity and shock are the most prominent diagnostic points. If there are bladder injuries, as far as first aid is concerned, the examination of the urine after the patient had voided is an indication that there may be bladder rupture. The observation of gross blood in the urine should be noted on the card attached to the patient and should be heavily underscored, since such injuries need immediate operation.

Penetrating Wounds.—Storck, in an article on "Penetrating Wounds of the Abdomen," published in the *Annals of Surgery* of May, 1940, says: "Eisberg stresses the importance of the study of the entrance and exit points, and he cites that bullet wounds of entrance are usually smaller than the caliber of the bullet, while the point of exit is more or less keyhole in shape and larger than the wound of entrance. He also draws attention to the fact that 'if an area of abrasion and contusion of the skin is concentric, it signifies that the bullet has taken a straight course and that the underlying viscera in this region are, in all probability, injured; if the area is to the right of the edge of the wound, it signifies that the missile has passed from right to left. Since the opposite side of this area is always undermined and this process, in turn, increases with the obliquity, the more superficial the bullet tract, the larger the area of abrasion and contusion and the greater the undermining. This observation is very important in differentiating superficial nonpenetrating wounds of the abdomen which cross the abdomen, causing pain and at times nausea, vomiting, tenderness, and rigidity.'"

If there are only wounds of entrance of small caliber, little first aid can be given except the noting, perhaps, of the assumed direction of the wound of entrance and the abdominal signs on examination. It is presumable that large eventations might occur. In this case it is advisable not to use iodine as a first-aid measure, since it is more apt to traumatize the peritoneum of the viscera. If one is positive that there is no perforation and if the intestines are on the abdomen, the doctor could apply sulfathiazole, replace the abdominal viscera, and tightly strap the abdomen, making note on the identification tag of the procedure. One must be sure, however, that there is no perforation of intestines that are protruding. If they are protruding and there is evidence of perforation, sulfathiazole should be applied

and the wound covered with a first-aid dressing.

If there is extensive bleeding from the abdomen one should observe whether or not this comes from the abdominal wall. If it does not, tight strapping of the abdomen in order to allow tamponade without interference with respiration is advisable.

Head Injuries

There is little one can do as far as scalp injuries are concerned unless there is massive scalp laceration. In such a case, control of bleeding, by ligature or clamp if necessary, is advisable. If the flaps can be easily raised it is advisable to observe whether or not there is fracture of the skull and whether or not the fracture is depressed. Sulfathiazole inserted beneath the scalp and the wound drawn gently over the defect, with a pressure bandage to prevent further hemorrhage, are justified.

Ivy and Stout have presented an excellent article on "The Emergency Treatment of the Face and Jaw," and I quote from them verbatim:

"The points demanding special attention in the combat area may be formulated as follows: (1) arrest of hemorrhage, (2) provision of adequate respiratory airway, (3) temporary approximate reduction and fixation of bone fragments, and (4) provision of safe transportation from the combat zone to hospital in the rear.

"(1) *Arrest of Hemorrhage.*—It may be possible to check hemorrhage temporarily by digital pressure over the artery proximal to the bleeding area. The principal points of compression about the head and neck are: external carotid artery—beneath anterior border of sternomastoid muscle just above level of thyroid cartilage; facial or external maxillary artery—lower border of mandible $\frac{3}{4}$ inch in front of angle; superficial temporary artery—just in front of the tragus of ear. Moderate hemorrhage from a wound about the jaw can usually be checked by pressure from a gauze pack inserted in the wound and held in place by a four-tailed bandage. Care must be exercised in the application of the pack and the bandage so as not to increase any respiratory difficulty occasioned by the nature of the wound itself. Hemorrhage that cannot be checked in this way demands a search for the bleeding vessel and an application of a clamp to it, followed by ligation if ligature material is available; otherwise, the clamp should be left on during transportation to the advanced hospital.

70 per cent of all chest wounds are complicated by hemothorax.

"Frequently, it occurs following crushing injuries of the chest with simple rib fractures and almost always it accompanies penetrating gunshot wounds and then may be called a 'compound' hemothorax.

"A compound hemothorax with small clean wounds of entrance and exit, as from rifle or machine gun bullets, and small penetrating shrapnel fragments or stab wounds should be treated like a simple closed pneumothorax. The important principle of therapy is aspiration with air replacement."

Nonpenetrating Wounds

"Nonpenetrating wounds of the chest may vary in extent from slight contusion of the chest wall to extensive crushing with multiple rib fractures and tear of the underlying lungs. Such injuries are common among persons buried in debris, in aviation accidents, and in sudden crushing injuries as when the victim is caught between a truck and a wall.

"Flying objects with violent impact on the chest wall may cause serious hemorrhage and laceration in the lung directly beneath the blow. Following a severe crushing of the chest there may be multiple rib fractures, which Barrett calls the 'stove-in' type. These injuries may be complicated by a traumatic asphyxia or an acute dilatation of the stomach with inability to get rid of the vomitus, which in turn favors the development of pneumonia and pulmonary suppuration. In this compression asphyxia the lesions may be symmetrical in both lungs with generalized congestion, some edema, and small subpleural hemorrhage and sometimes emphysema along the line of the ribs; or there may be laceration or fracture of the trachea, bronchi, or lungs."

Blast Injuries

"In the English literature considerable attention has been given to the blast injury or concussion and cases have been reported in detail by Dean and Thomas, Falla, Fallon, and Hadfield and Christie. The first experimental work was reported in 1924 by Hooker, who said that bruising and rupture of the lungs 'were the single gross lesions found postmortem after exposure to air concussion due to gun blast or high explosive.' Blast produces a sudden marked fall of arterial and venous pressures and a later washing out of venous carbon dioxide. Since the onset of the present war further studies have been made under the direction of the Home Office

by Bancroft with goats, and by Zuckerman with mice, pigeons, guinea pigs, rabbits, and monkeys.

"Zuckerman's work is of sufficient interest to report in detail. He used a 70-pound charge of high explosive and first explains the physics of a blast. Blast consists of two waves: a compression wave that lasts 0.006 seconds and a suction wave of 0.03 seconds. All pressures are, of course, in excess of the normal atmospheric pressure of 15 pounds per square inch. The blast wave consists of a shell of compressed gas increasing very rapidly in radius—1,500 feet a second at 30 feet for a 60-pound charge. There is an additional wind pressure exerted by this shell of gas *only* in the direction of its motion; hence, any surface not directly in its path is subject just to the compression wave. This wave of pressure is highest in the region of the explosion and falls rapidly. At 15 feet from a 125-pound charge the compression wave carries a pressure of 200 pounds. Close to the explosion the wind pressure may be as great as the pressure of the charge itself, but it falls more quickly with distance. Thus, everything in the immediate neighborhood of a big bomb is suddenly exposed to a wave of many times the atmospheric pressure, whereas at 50 feet this will be only two or three atmospheres and at 100 feet only a fraction of an atmosphere. The velocity and duration of the pressure wave is such that a human body will be completely immersed in it. The suction wave is much weaker and can never exceed 15 pounds per square inch, which is a perfect vacuum. The magnitude of the pressure and suction vary directly with the amount of explosive. If an object is not blown apart by the wind and compression waves, it may then be attracted to the center of the explosion by the weaker and longer suction wave.

"If the victim of a bomb explosion is not blown apart he may be injured in three ways: (1) by being hit by masonry, fragments, or flying objects; (2) by being violently thrown; or (3) by the effect of the blast wave without being thrown. This last is the true blast injury or concussion in which there is no sign of any external injury, and even in this group Roberts warns of confusion with carbon monoxide poisoning.

"In his work with animals with the 70-pound blast Zuckerman found that no animal died that was more than 18 feet from the explosion and none more than 50 feet distant was injured. Furthermore, there was no sign of external injury in any of the animals

"At the December, 1941, meeting of the Royal Society of Medicine, Mr. Thomas in his discussion quoted Hoche's review of 11,000,000 English, French, American, and German wounded."

"The high immediate and late mortality of wounds in the thorax is evident from the above tables. Patients with injuries of the chest suffer from the same shock, hemorrhage, and sepsis as those with wounds elsewhere, *plus* special factors which interfere with their respiratory and cardiorespiratory function and reserve. These are: (1) air and blood in one or both pleural cavities, frequently under increasing tension; (2) open pneumothorax with lung collapse, mediastinal flutter, paradoxical respiration with swing of the intrapulmonary air from one lung to the other and loss of the aspiratory effect on the great veins with decreased cardiac output; (3) cardiac tamponade; and (4) surgical emphysema, sometimes progressive. All of these features become accentuated in older people and in those with existing lung or heart pathology."

General Treatment of Injuries

"Before taking up specific types of wounds certain basic factors of treatment should be understood. First, almost all patients with wounds of the thorax suffer from shock and some also from hemorrhage. If there is a sucking wound present, this should be promptly sealed with a sterile pad strapped snugly in place or, if this is not available, with anything at hand. Hemorrhage from intercostal vessels or the parietes may be temporarily controlled by a mushroom type

of pack which is inserted into the wound and pulled outward, thus exerting pressure from the inside. The Shaeffer method of artificial respiration should be used with care, as the manipulation may cause further injury to the chest wall or lungs. The legs should be elevated to combat shock and the patient transported in the Trendelenberg position unless it is evident that this causes respiratory embarrassment, in which case the stretcher should be slightly elevated.

"Morphine should be used as needed to allay pain and fear. It should not be given in such dosage as will depress respiration or productive cough, however, for the maintenance of good pulmonary ventilation and the ability to cough up secretions is essential. In the case of rib fractures, particularly when they are multiple, injections of 2 to 5 per cent novocaine into the intercostal nerves paravertebrally or at the site of fracture are most effective and may be repeated as necessary." (Strapping is advisable if only one side of the thorax is involved.)

"Not infrequently the abdomen is held rigidly in wounds of the lower chest and, here, the decision must be made as to whether or not there is accompanying intra-abdominal, renal, or spinal injury, sometimes an extremely difficult differentiation.

"There are certain indications for immediate operative intervention, the most urgent of which is a wound of the heart with acute cardiac compression. This is first suggested by wounds close to the sternum and the diagnosis is made by (1) a falling or absent blood pressure, (2) distended veins of the neck with increased venous pressure, and (3) a silent heart by auscultation." (If a wound of the heart is suspected this patient should be given preference in transportation.)

"Progressing hemorrhage in wounds of the chest requires operation. Generally, this is due to injured intercostal or internal mammary vessels, less often to trauma of the lung itself.

"Wounds of the entrance and exit should be carefully explored so that the intercostal vessels may be carefully inspected, as these are the usual sources of persisting hemorrhage.

"If available, sterile sulfanilamide or sulfathiazole powder may be left in the pleural cavity and soft parts in 6-, 8-, or 10-Gm. amounts as prophylaxis against infection."

Hemothorax

"According to Edwards and Davies about

WORK

A Song of Triumph

ANGELA MORGAN

Work!

Thank God for the might of it,
The ardor, the urge, the delight of it—
Work that springs from the heart's desire,
Setting the brain and the soul on fire—
Oh, what is so good as the beat of it,
And what is so good as the heat of it,
And what is so kind as the stern command,
Challenging brain and heart and hand?

Work!

Thank God for the pride of it,
For the beautiful, conquering tide of it,
Sweeping the life in its furious flood,
Thrilling the arteries, cleansing the blood,
Mastering stupor and dull despair,
Moving the dreamer to do and dare.
Oh, what is so good as the urge of it,
And what is so glad as the surge of it,
And what is so strong as the summons deep,
Rousing the torpid soul from sleep?

Work!

Thank God for the pace of it,
For the terrible, keen, swift race of it;
Fiery steeds in full control,

Nostrils aquiver to greet the goal.
Work, the power that drives behind,
Guiding the purposes, taming the mind,
Holding the runaway wishes back,
Reining the will to one steady track,
Speeding the energies faster, faster,
Triumphing over disaster.
Oh, what is so good as the pain of it,
And what is so great as the gain of it?
And what is so kind as the cruel goad,
Forcing us on through the rugged road?

Work!

Thank God for the swing of it,
For the clamoring, hammering ring of it,
Passion of labor daily hurled
On the mighty anvils of the world.
Oh, what is so fierce as the flame of it?
And what is so huge as the aim of it?
Thundering on through the dearth and doubt,
Calling the plan of the Maker out.
Work, the Titan; Work, the friend,
Shaping the earth to a glorious end,
Draining the swamps and blasting the hills,
Doing whatever the Spirit wills—
Rending a continent apart,
To answer the dream of the Master heart.
Thank God for a world where none may shirk—
Thank God for the splendor of work!

NEW YORK PHYSICIANS TO HOLD SUPPER-DANCE AT SHERRY'S TO AID AMERICAN HOSPITAL IN BRITAIN

The Physicians' Committee of Greater New York is holding a Supper-Dance at Sherry's on Washington's Birthday Eve, February 21, to raise funds to help maintain the American Hospital in Britain, which is entirely staffed by American doctors, nurses, and technicians, and all of whose equipment is American-made. This benefit to aid the "American Hospital in Britain" is a new venture for the Physicians' Committee, which heretofore has raised a considerable sum to aid many of the voluntary hospitals.

Dr. Adolph G. DeSanctis is chairman of the Physicians' Committee of Greater New York, with Dr. B. Wallace Hamilton as secretary, Dr. Kirby Dwight as treasurer, and Drs. Chas. Gordon Heyd, Nathan B. Van Etten, John E. Jennings, H. P. Mencken, and Herbert A. Cochran as vice-chairmen of the five boroughs of

Greater New York. Mrs. W. Coda Martin, the director of the Medical Department of the British War Relief Society, Inc., is campaign director.

There will be dancing, cards, a buffet supper, as well as a Game Room. A U. S. Defense Bond, the main prize, will add a patriotic touch. One of the most unique and interesting events of the evening will be a Cabaret in which the doctors themselves will participate.

This Supper-Dance is being sponsored entirely by doctors and their families and friends. Already one-fifth of the tickets have been sold, and much enthusiasm is being shown by the medical profession in this affair.

Tickets may be purchased and tables reserved at the Medical Aid Department, British War Relief Society, 730 Fifth Avenue.

Foreigners listening to our radio must be astonished to hear such heart-stirring eloquence wasted on laxatives.

Customer: "Do you have anything for gray hair?"

Druggist: "Nothing, sir, but the greatest respect."

—Medical Record

examined. The outstanding pathological condition consisted of hemorrhages in both lungs and in all lethal cases blood was present in the bronchial tree and air passages. The blood comes from torn alveolar capillaries as a rule. There was bruising and tearing of the lungs in the lines of the ribs, this bruising extending for a short distance into the parenchyma. Zuckerman concluded that these pulmonary lesions were caused by the pressure component of the blast by its impact with the body wall. This concussion was based on the type of lesions found and further on the fact that animals encased in thick sponge rubber suffered little damage from the blast compared with their controls; also animals with one-half of their bodies protected by rubber sustained these lesions only on their unprotected sides when they were exposed with this side facing the blast and not on the protected side when this was the side exposed to the blast.

"In the clinical cases similar findings have been recorded. After blast concussions symptoms may be delayed in appearance up to two to five days and consist of tachycardia, restlessness, dyspnea, and cough with blood-tinged sputum. The signs are a fullness of the lower chest with diminished movement of the diaphragm, some spasticity of the upper abdomen, dullness and rales at the base of the lungs, and a loss of translucency by x-ray with evidence of diminished rib expansion. The treatment is absolute rest, sedation, and oxygen therapy."

Mr. Broster states: "At autopsy, hemorrhage of varying degree is found in the lungs. Hemorrhages may also occur in other organs, such as the liver and spleen, intestine, adrenals, kidney, bladder and, seldom, the brain. There is some evidence to suggest that the lung effect is due to sudden compression of the chest wall, and bleeding into the lung capillaries may go on for some days. The force of the blast may hurl people against objects and give rise to injuries from such a blow, and fat embolism has also been found in the lung. From the surgical aspect this syndrome is associated with rigidity in the abdomen, and this point needs emphasis to prevent unnecessary celiotomy and caution so as not to overlook coincident injury to the intestine."

Burns

War has made so many revolutionary changes in the treatment of burns that I approach this subject with considerable hesitation.

After the patient has reached the hospital there is a general agreement that the shock, and later hypoproteinemia, is best treated by plasma transfusion, often of considerable magnitude, accompanied by adrenal cortex medication for shock. And, later, almost everyone agrees that the granulating surfaces should be skin-grafted as soon as possible in order to combat dehydration and, second, anemia. What, however, should be the immediate first-aid treatment?

It is obvious, I believe, that first aid, except for treatment of shock by morphine and warmth, should not be given in a first-aid station unless transportation is to be considerably delayed.

The primary treatment of the shock should be associated with the primary debridement and local treatment of the burned surfaces. It is often better to remove the burned clothing in the hospital, if possible, than to strip it off in a poorly ventilated and drafty first-aid shelter. Often the clothing is stuck to the skin and new shock is produced by the primary first-aid treatment.

The problem of the local treatment after the patient reaches the hospital depends upon whether one prefers the formation of an eschar in order to splint the burn and diminish the pain of dressing or whether one prefers the so-called open method, which means that no effort is made to create an eschar.

In the first-aid kits both tannic acid powder and picric acid are supplied. If it is necessary to do first-aid treatment, one must avoid the use of ointments, and probably the best first aid would be sprinkling the burned surface with sulfathiazole and then applying a wet dressing of freshly made 5 per cent tannic acid. Notable exceptions to this treatment should be burns of the hands and face, where amertan can be utilized instead of the wet dressing. Amertan is in a water base and does not create the firm eschar that the aqueous solution of tannic acid does. It would be inadvisable to go further into the local treatment of burns in the hospital at this time, since it has nothing to do with first aid.

Finally, in conclusion, I should like to quote a poem, written, strangely enough, in 1917 when we were entering a world crisis similar to the one today. This was written by Angela Morgan, and to my mind, it epitomizes the job of each member of the medical profession, whether he is in the uniform of the armed forces, whether he is working on a draft board, or whether he is serving the civil population.

Medical Preparedness

Occupational Deferments of Medical Doctors, Dentists, and Doctors of Veterinary Medicine

The memorandum published below is for the information and guidance of all physicians of the State of New York.

COL. SAMUEL J. KOPETZKY,
New York State Chairman,
Procurement and Assignment Service

NATIONAL HEADQUARTERS
SELECTIVE SERVICE SYSTEM,
WASHINGTON, D. C.
21st and C Streets, N. W.

January 28, 1942

Memorandum to All State Directors (I-363)

Local Board Release (89)

Subject: Occupational Deferments of Medical Doctors, Dentists, and Doctors of Veterinary Medicine (III)

Information previously distributed by this Headquarters clearly indicates an overall shortage of medical doctors, dentists, and doctors of veterinary medicine in the Nation. Since war was declared, the shortage of these professional men has become acute. It is now manifest that every qualified doctor, dentist, and veterinarian must serve where he can render the greatest professional service to the Nation.

In order to accomplish this purpose, the President, by Executive Order, has formed the Procurement and Assignment Service, under the Office of Defense Health and Welfare Services. This Service was formed primarily for the purpose of gathering and making available information with respect to the supply of qualified practitioners in the fields of medicine, dentistry, and veterinary medicine, with a view of securing the most effective allocation of medical man power as indicated by the requirements of the armed forces, civilian needs, and industrial medicine.

To work with the headquarters of this Service in Washington, there is being organized a committee for each Corps Area in the Continental United States. Each committee will consist of five doctors, two dentists, and one veterinarian.

The committees have been accepted as advisors to the nine Corps Area Surgeons, to the Naval District Surgeons, and to the Regional Medical Officers of the Office of Civilian Defense and will operate not only through the subdivisions of the medical, dental, and veterinary associations but also with the profession at large in securing information and giving advice.

When considering the classification of any registrant who is a qualified medical doctor, dentist, or doctor of veterinary medicine, the Director of Selective Service desires that Local Boards, through the State Director, shall consult the Procurement and Assignment Committee of the Corps Area for information as to the availability of qualified medical doctors, dentists, and doctors of veterinary medicine in the community. This information shall be considered by the local board in determining the registrant's classification. The Executive Order referred to in no way affects the authority of the Selective Service System to classify registrants. The procedure has been established for the purpose of making such information available to local boards.

For the convenience of the State Director and the local boards, the names and addresses of the Chairmen of the nine Corps Area Committees of the Procurement and Assignment Service are listed below:

First Corps Area.....
*Second Corps Area—Dr. A. W. Booth, Elmira,
New York.

Third Corps Area.....
Fourth Corps Area.....
Fifth Corps Area.....
Sixth Corps Area.....
Seventh Corps Area.....
Eighth Corps Area.....
Ninth Corps Area.....

Sincerely yours,

LEWIS B. HERSHEY, *Director*

* Dr. A. W. Booth, Elmira, New York, has established temporary offices at the Headquarters of the Medical Society of the State of New York at 292 Madison Avenue, New York City, where he may be addressed.

PREMEDICAL AND MEDICAL STUDENTS

Opportunity for Appointments as Ensigns in Class H-V(P) United States Naval Reserve

THE Secretary of the Navy recently approved a change in Navy regulations whereby it is now possible for those premedical students who have been accepted for entrance to, and all medical students in, Class "A" medical colleges, to be appointed in the United States Naval Reserve in Class H-V(P), provided they

meet the physical and other requirements for such appointment.

Students who are acceptable will be given provisional commissions as Ensigns, and it is the policy of the Bureau of Medicine and Surgery not to nominate such officers for active duty until after they have completed their prescribed

Maternal Welfare

From time to time under this heading articles will appear on obstetric subjects which are deemed of importance as aids to improvement of maternal welfare in New York State. The members of the Committee are Charles A. Gordon, M.D., chairman; Alexander T. Martin, M.D.; James K. Quigley, M.D.; and Ferdinand J. Schoeneck, M.D.

Standards for the Care of Pregnancy Complicated by Heart Disease

THE following article on heart disease in pregnancy was first published by the Committee on Maternal Welfare of the Medical Society of the County of Kings in 1938. The standards were revised in 1941. The first portion of the article is herewith reproduced; the remainder will appear in the March 1 issue.

Usual Types of Heart Disease Complicating Pregnancy

About 7 per cent of women have heart murmurs when they are examined during pregnancy. The majority of these murmurs do not indicate heart disease. They are known as functional murmurs and are purely incidental findings without pathologic significance.

The majority of these functional murmurs are systolic in time. They may be heard at all valve areas. When the patient is studied more carefully by x-ray examination of the heart, no abnormal change in the size or shape may be detected. Women with these murmurs bear pregnancy well because there is no cardiac pathology. A good proportion of these murmurs disappear after the pregnancy.

Organic disease of the heart occurs in about 1 per cent of pregnant women in this locality. About 90 per cent of the lesions encountered are due to rheumatic heart disease. The remaining cardiac lesions will include congenital abnormalities, syphilis, cardiovascular disease, arteriosclerosis, and hypertensive heart disease.

All the rheumatic cases may not give a history of rheumatic fever. The most frequent rheumatic lesion encountered is mitral stenosis, with or without mitral insufficiency.

When organic disease of the heart exists, there is usually a diastolic or presystolic murmur present, with or without a systolic murmur. This finding is most important in recognizing a diseased heart.

There will also be noticed some change in size and shape of the heart on an x-ray examination. When a systolic murmur occurs alone, it must be associated with some change in the size or contour of the heart before a diagnosis of organic disease is made, even if there is a history of rheumatic fever.

Classification of Heart Disease*

Functional Capacity

Classification of Patients.—*Class I:* Patients with cardiac disease and no limitation of physical

activity. Ordinary physical activity does not cause discomfort. Patients in this class do not have symptoms of cardiac insufficiency, nor do they experience anginal pain.

Class II (formerly II-A): Patients with cardiac disease and slight limitation of physical activity. They are comfortable at rest. If ordinary physical activity is undertaken, discomfort results in the form of undue fatigue, palpitation, dyspnea, or anginal pain.

Class III (formerly II-B). Patients with cardiac disease and marked limitation of physical activity. They are comfortable at rest. Discomfort in the form of undue fatigue, palpitation, dyspnea, or anginal pain is caused by less than ordinary activity.

Class IV (formerly III): Patients with cardiac disease who cannot carry on any physical activity without discomfort. Symptoms of cardiac insufficiency or of the anginal syndrome are present even at rest. If any physical activity is undertaken, discomfort is increased.

Therapeutic Classification.—*Class A:* Patients with cardiac disease whose physical activity need not be restricted.

Class B: Patients with cardiac disease whose ordinary physical activity need not be restricted but who should be advised against unusually severe or competitive efforts.

Class C: Patients with cardiac disease whose ordinary physical activity should be moderately restricted and whose more strenuous habitual efforts should be discontinued.

Class D: Patients with cardiac disease whose ordinary physical activity should be markedly restricted.

Class E: Patients with cardiac disease who should be at complete rest, bed or chair.

Potential Heart Disease.—Patients in whom no cardiac disease is discovered, but whose course should be followed by periodic examinations because of the presence or history of an etiologic factor that might cause heart disease. The diagnosis in these cases is potential heart disease. The etiologic diagnosis should also be recorded.

Possible Heart Disease.—Patients with symptoms or signs referable to the heart but in whom a diagnosis of cardiac disease is uncertain should be classified tentatively as possible heart disease. When there is a reasonable probability that signs or symptoms are not of cardiac origin, a diagnosis of possible heart disease should not be made. Re-examination after a suitable interval will usually establish a definite diagnosis.

* According to the New York Heart Association as approved by the American Heart Association.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York will henceforth be published in this section of the JOURNAL. Members of the committee are Oliver W. H. Mitchell, M.D., chairman; George Baehr, M.D.; and Charles D. Post, M.D.

General Medicine

A course in General Medicine has been arranged by Dr. Walter W. Palmer, College of Physicians and Surgeons, Columbia University, New York City, for the *Columbia County Medical Society*. The lectures will be given on Thursday evenings, 8:30 p.m., at the Hudson City Hospital in Hudson, New York.

March 12.—The Modern Treatment of Diabetes
H. Rawle Geyelin, M.D., associate clinical professor of medicine, College of Physicians and Surgeons, Columbia University.

March 26.—Syphilis.

James Lowery Miller, M.D., instructor in dermatology, College of Physicians and Surgeons, Columbia University.

April 9.—The Diagnosis and Treatment of Anemia.

Paul Reznikoff, M.D., associate professor of clinical medicine, Cornell University Medical College, New York City.

April 23.—Hypertension and Hypertensive Heart Disease.

William Goldring, M.D., associate professor of medicine, New York University College of Medicine, New York City.

May 7.—Asthma.

Albert Vander Veer, M.D., consultant in allergy, Roosevelt Hospital, and assistant director, Allergy Clinic, New York City.

May 21.—Rheumatic Fever.

Homer F. Swift, M.D., Hospital of the Rockefeller Institute for Medical Research, New York City.

June 4.—Nephritis.

John D. Lytle, M.D., assistant professor of pediatrics, College of Physicians and Surgeons, Columbia University.

The lectures on "Syphilis" and "Rheumatic Fever" are given in cooperation with the State Department of Health and the New York State Medical Society.

A course in General Medicine, arranged by Dr. Albert F. R. Andresen, Long Island College of Medicine, Brooklyn, for the *Madison County Medical Society* is being given on Tuesday evenings, at 8:30 p.m., at the Hotel Oneida, Oneida, New York. (It is a course of clinical lectures illustrated by clinical material furnished by the group addressed.) This course may also be given in the form of regular lectures illustrated by lantern slides and tables.

February 3.—Practical Considerations of Blood Dyscrasias.

Eugene R. Marzullo, M.D., clinical professor of medicine, Long Island College of Medicine.

February 10.—Diabetes: Its Modern Interpretation and Treatment.

M. B. Handelsman, M.D., assistant clinical

professor of medicine, Long Island College of Medicine.

February 17.—Treatment of Gallbladder Disease.

Albert F. R. Andresen, M.D., professor of clinical medicine, Long Island College of Medicine.

Sulfonamide Therapy

A course on Sulfonamide Therapy of three two-hour sessions was arranged by the Council Committee on Public Health and Education, Medical Society of the State of New York and the New York State Department of Health for the *Oneida County Medical Society*. The lectures were held at the Utica State Hospital.

First Session: Tuesday Evening, January 20.

1. Behavior of Sulfonamides in the Body and Principles for Their Use.

David D. Rutstein, M.D., director, Cardiac Bureau, State Department of Health, and assistant professor of medicine, Albany Medical College, Albany, New York.

2. Local and Internal Use of Sulfonamides in Surgery.

J. Ernest Delmonico, M.D., associate professor of clinical surgery, Syracuse University, College of Medicine, Syracuse.

Second Session: Tuesday Evening, January 27.

1. Treatment of Genitourinary Infections in the Male.

Thomas F. Laurie, M.D., associate professor of urology, Syracuse University College of Medicine, Syracuse, New York.

2. Sulfonamides in Obstetrics and Gynecology.

Ferdinand J. Schoeneck, M.D., assistant professor of clinical obstetrics, Syracuse University College of Medicine, Syracuse.

Third Session: Tuesday Evening, February 3.

1. Treatment of Pneumonia.

Joseph J. Bunim, M.D., instructor in medicine, New York University College of Medicine, Brooklyn.

2. Treatment of Meningitis.

A. Clement Silverman, M.D., professor of clinical pediatrics, Syracuse University College of Medicine, Syracuse, New York.

This instruction is a cooperative endeavor between the New York State Department of Health and the State Medical Society.

A course in Sulfonamide Therapy of three two-hour sessions was arranged by the Council Committee on Public Health and Education, Medical Society of the State of New York and the New York State Department of Health for the *Jefferson County Medical Society*. The lectures were as follows:

medical studies and shall have served one year's satisfactory internship in a civilian hospital accredited for intern training, or shall have been accepted as Acting Assistant Surgeon in the Navy for intern training.

Upon graduation, and when the Bureau has been informed of this fact by the Dean, commissions as Lieutenant (junior grade) MC-V(G), U.S.N.R., will be issued to provisional Ensigns and, after serving their internship in nonnaval hospitals, they will be nominated for active duty. Application for, or acceptance of, either a provisional or permanent commission in the Naval Reserve, does not preclude the possibility of applying for a commission in the Medical Corps of the regular Navy. Persons affiliated with the Naval Reserve are not subject to induction into Army service by action of local Selective Service Boards.

Navy regulations require that all applications for appointments in the Naval Reserve be filed with the Commandant of the Naval District in which the applicant resides. The address of the Commandant of your district may be obtained from the Dean of your college.

Application forms may be obtained from the Dean's office or from someone designated by him, upon request from the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., or from the Commandant of your Naval District. When your application form has been properly completed, it, together with the other credentials indicated on the application form, should be mailed to the Commandant of your Naval District. He will instruct you relative to obtaining a physical examination, fingerprints, etc.

In the case of a premedical student, it is necessary to enclose with your application for appointment a statement, signed by the Dean of a medical college, to the effect you have been accepted as a first-year medical student in a Class "A" school for the next entering class.

It is the understanding of the Bureau of Medicine and Surgery that Selective Service Boards will accept a statement from the Commandant of your Naval District to the effect that your application is on file as basis for deferment until your application has received final action.

The following appeared in the Journal of the Medical Society of the County of New York January 24, 1942. In the other counties in Greater New York similar arrangements are being made. It is urged by the Emergency Medical Service of the Office of Civilian Defense that all physicians in the five counties enroll with their county societies in aid of this service.—
Editor

Emergency Medical Service Gives Role of Physician in Civilian Defense

THE following plan for the guidance of the medical profession in New York County has been approved by Dr. Edward M. Bernecker, Chief of Emergency Medical Service for the New York Area:

A. As to all physicians.

1. Each physician is requested to register by mail for Civilian Defense with the New York County Medical Society, 2 East 103rd Street. Such registration will be made available to Central and Local Stations under the Office of Civilian Defense. This registration should include each doctor's name, age, specialty, office address and telephone number, office hours, home address and telephone number.

2. Each Local Control Station will thus be furnished with a list of physicians within its area who shall be subject to call and despatch where needed, in the event of air raid or local catastrophe.

3. Each physician registered is to be provided with an identification card from the Office of Civilian Defense to be honored by police and wardens, but used as a pass only when the physician is called by his Control Station.

B. As to Chiefs of Emergency Medical Service, members of hospital staffs, and of Emergency Field Units.

1. Designated medical officials under Office of Civilian Defense will be provided with distinctive arm bands and automobile insignia to permit free movement in time of emergency.

2. Each authorized hospital staff physician

will be provided with an identifying arm band (O.C.D. Medical Corps design), to be used as a pass only when he is called to his hospital at such time as the Emergency Field Unit of his hospital is sent out, or when his hospital is designated to receive casualties.

C. As to physicians not affiliated with hospitals.

1. The duty of such physicians is to remain at office or home unless ordered to specific duty by Control Station.

2. To await such call, responding when needed for:

a. Assistance or replacement for Casualty Station.

b. Assistance or replacement for hospital staff.

c. Duty at First-Aid Post.

3. In event of a nearby catastrophe a physician's office may be employed as a First-Aid Post.

4. If neither at home nor office at the time of raid, physician should remain where he is to give local aid if needed until he can be summoned officially to other duty or return to his office or home.

Physicians of New York County who desire to serve under Civilian Defense and to receive identification cards are requested to mail to the office of the Medical Society of the County of New York the information requested in Paragraph A-1 above.

CONDUCT W. CUTLER, JR., M.D., Chief,
Emergency Medical Service, New York County

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York will henceforth be published in this section of the JOURNAL. Members of the committee are Oliver W. H. Mitchell, M.D., chairman; George Baehr, M.D.; and Charles D. Post, M.D.

General Medicine

professor of medicine, Long Island College of Medicine.

February 17.—Treatment of Gallbladder Disease.

Albert F. R. Andresen, M.D., professor of clinical medicine, Long Island College of Medicine.

Sulfonamide Therapy

A course on Sulfonamide Therapy of three two-hour sessions was arranged by the Council Committee on Public Health and Education, Medical Society of the State of New York and the New York State Department of Health for the *Oneida County Medical Society*. The lectures were held at the Utica State Hospital.

First Session: Tuesday Evening, January 20.

1. Behavior of Sulfonamides in the Body and Principles for Their Use.

David D. Rutstein, M.D., director, Cardiac Bureau, State Department of Health, and assistant professor of medicine, Albany Medical College, Albany, New York.

2. Local and Internal Use of Sulfonamides in Surgery.

J. Ernest Delmonico, M.D., associate professor of clinical surgery, Syracuse University, College of Medicine, Syracuse.

Second Session: Tuesday Evening, January 27.

1. Treatment of Genitourinary Infections in the Male.

Thomas F. Laurie, M.D., associate professor of urology, Syracuse University College of Medicine, Syracuse, New York.

2. Sulfonamides in Obstetrics and Gynecology.

Ferdinand J. Schoeneck, M.D., assistant professor of clinical obstetrics, Syracuse University College of Medicine, Syracuse.

Third Session: Tuesday Evening, February 3.

1. Treatment of Pneumonia.

Joseph J. Bunim, M.D., instructor in medicine, New York University College of Medicine, Brooklyn.

2. Treatment of Meningitis.

A. Clement Silverman, M.D., professor of clinical pediatrics, Syracuse University College of Medicine, Syracuse, New York.

This instruction is a cooperative endeavor between the New York State Department of Health and the State Medical Society.

A course in Sulfonamide Therapy of three two-hour sessions was arranged by the Council Committee on Public Health and Education, Medical Society of the State of New York and the New York State Department of Health for the *Jefferson County Medical Society*. The lectures were as follows:

First Session: Tuesday, January 27, 1942, at 7:30 P.M. Mercy Hospital, Watertown, New York.

1. Behavior of Sulfonamides in the Body and Principles for Their Use.

Alexander D. Langmuir, M.D., Deputy Commissioner, County of Westchester Department of Health, Peekskill, New York.

2. Local and Internal Use of Sulfonamides in Surgery.

Leon E. Sutton, M.D., associate professor of clinical surgery, Syracuse University College of Medicine, State Tower Building, Syracuse, New York.

Second Session: Thursday, February 12, 1942, at 6:30 P.M. Black River Valley Club, Watertown, New York.

1. Treatment of Genitourinary Infections in the Male.

Allister M. McLellan, M.D., instructor in urology, Cornell University Medical College, 121 East 60th Street, New York City.

2. Sulfonamides in Obstetrics and Gynecology.

Edward C. Hughes, M.D., professor of clinical obstetrics, Syracuse University College of Medicine, 713 East Genesee Street, Syracuse, New York.

Third Session: Tuesday, February 24, 1942, 7:30 P.M. Mercy Hospital, Watertown, New York.

1. Treatment of Pneumonia.

Clayton W. Greene, M.D., professor of medicine, University of Buffalo, School of Medicine.

2. Treatment of Meningitis.

Harry Bakwin, M.D., associate professor of pediatrics, New York University Medical College.

This instruction is a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of New York.

Cancer Teaching Day Held in Syracuse

The Cancer Teaching Day held at Syracuse on January 17 was attended by physicians from all parts of the state. A well-arranged program was presented under the auspices of the following organizations:

Tumor Clinic Association of the State of New York

Syracuse University College of Medicine
Medical Society of the State of New York
Division of Cancer Control of the New York State Department of Health.

The Council of the Tumor Clinic Association held a morning session and luncheon at the University Club of Syracuse. The members of the Council are: Drs. Frederick S. Wetherell, president, Syracuse; Andrew H. Bowdy, vice-president, Rochester; Clyde L. Randall, secretary and treasurer, Buffalo; Arthur A. Hobbs, Jr., Ogdensburg; Arthur C. Martin, Hempstead; Karl F. Eschelman, Buffalo; Leslie R. Lingeman, Rochester; J. Howard Ferguson, Syracuse; Arthur F. Holding, Albany; James Greenough, Oneonta; and C. O. Davison, Poughkeepsie.

The afternoon meeting was held in the auditorium of Syracuse University College of Medicine. At this session an attentive audience of more than 250 listened to an instructive program, ably presented. Dr. Frederick S. Wetherell, president of the Tumor Clinic Association, presided. Dr. Herman G. Weiskotten, dean, Syracuse University College of Medicine, welcomed the physicians and expressed his interest in and desire to assist the graduate medical education program as now given in New York State through the cooperation of the Medical Society of the State of New York, the New York State Department of Health, the medical schools, and many other medical and public health groups.

Dr. Bowman C. Crowell, associate director, American College of Surgeons, spoke on "The Role of Tumor Clinics in Cancer Control," with discussion by Dr. Louis C. Kress, director, Division of Cancer Control, State Department of Health.

Dr. Lloyd F. Craver, attending physician, Memorial Hospital, New York City, spoke on "The General Practitioner and the Diagnosis of Cancer," followed by a discussion by Dr. Karl F. Eschelman, director, Tumor Clinic, and Edward J. Meyer, Memorial Hospital, Buffalo.

Dr. John J. Morton, Jr., professor of surgery, University of Rochester School of Medicine, discussed the topic of "Advances in Surgical Treatment of Cancer," followed by a discussion by Dr. George W. Cottis, president-elect of the Medical Society of the State of New York.

Dr. J. Howard Ferguson, associate professor of Pathology, Syracuse University College of Medicine, talked on "Biopsy-Indications and Methods." This was followed by a discussion by Dr. Rudolph J. Shafer, director of laboratories, Steuben County, Corning. The papers were followed by a general discussion, questions, and an exchange of ideas.

A social hour at Hotel Syracuse followed the afternoon meeting. Refreshments were provided by the Local Committee on Arrangements. These physicians are to be highly congratulated for their part in making the Cancer Teaching Day such an enjoyable occasion.

One hundred sixty-one physicians attended the dinner held at the Hotel Syracuse. Dr. O. W. H. Mitchell presided at the scientific session. Opening remarks were made by Dr. Edward S. Godfrey, Jr., commissioner of health, the State of New York. Dr. Godfrey stressed the importance of cooperative endeavor and teamwork and expressed his appreciation of the postgraduate education program of the State Medical Society in which the State Department of Health willingly and gladly participates.

Dr. G. Allen Robinson, Director, Tumor Clinic, Flower and Fifth Avenue Hospitals, New York City, and Dr. Walter T. Murphy, Radiologist, State Institute for the Study of Malignant Diseases, discussed the subject of "Principles of Radium and X-Ray Therapy." Dr. Byrl R. Kirklin, chief, Section of Roentgenology, Mayo Clinic, Rochester, Minnesota, discussed the subject of "X-Ray as a Diagnostic Aid in Cancer." These instructive and interesting talks were illustrated with lantern slides.

Those in charge of this Teaching Day expressed the hope that more state-wide cancer meetings will be held in other cities in New York.

COLLOIDAL IRON VS IONIZABLE IRON

NON-IONIZING—EASILY ASSIMILABLE

FOR
THE
PALE
CHILD

IRON SALT IONS MAY IRRITATE STOMACH

IN the run down child, anemia and malnutrition are usually combined with digestive malfunction. In combating this triumvirate, colloidal iron has many therapeutic advantages over the iron salts. The salts (sulphates, citrates, etc.) are split up by the gastric juice with the release of ions likely to produce astringent and irritating effects. In the intestine, the iron ions form precipitates which are therapeutically inert, highly dehydrating, and constipating.

But the iron in OVOFERRIN is *colloidal iron protein*—not in ionic form. It is little affected by the gastric juice. It is stable and cannot irritate. Indeed it actually appears to stimulate the appetite. Most nutri-

ment must be in the colloidal state to be absorbed. OVOFERRIN arrives in the intestines as a colloidal hydrous oxide which is readily assimilable and does not dehydrate or constipate.

Particularly important in the young patient, OVOFERRIN is practically odorless and tasteless and can stain tongue or teeth no more than can an iron nail. Its palatability is the result of its colloidal state and not due to sweetening or masking.

Prescribe OVOFERRIN also in secondary anemia, convalescence and pregnancy. Supplied in 11 oz. bottles: dose one tablespoonful at meals and bedtime in milk or water. Write for professional sample.

Medical News

Traffic Regulations Eased for Doctors

ASISTANT Chief Inspector, J. J. Sheehy, Police Department, City of New York, has advised the Chairman of the Coordinating Council of the Five County Medical Societies of Greater New York, that an order has been issued to police officials directing the recognition of M.D. license plates as evidence that the automobile belongs to a practicing physician. Heretofore only the official cards and insignia of the county medical societies were recognized by the police.

In the future police and traffic patrolmen will extend courtesy to physicians when their cars are

in use for professional purposes, such as making calls at the home of patients, attending hospitals and clinics, or participating in defense activities. Inasmuch as physicians' services will be required at any time of the day or night, in the event of an emergency, it may be necessary for physicians to park their cars in front of their homes or offices, if their garages are not in the immediate vicinity.

Official insignia will probably be issued by the defense authorities in the near future to cover physicians engaged in this work and to enable the police to recognize such a physician's car as in emergency use.

County News

Bronx County

The January meeting was held on the twenty-first at Burnside Manor, 85 West Burnside Avenue. Following the executive session Dr. George Ernest Binkley gave a talk on "The Diagnosis and Treatment of Cancer of the Rectum." Discussion was by Dr. Joseph Felsen and Dr. Edward R. Cunneiff.

"Cancer of the Colon and Rectum" was the subject of a scientific exhibit which was divided into three sections: radiographic, pathologic, and proctologic.

Chautauqua County

The following officers were elected at the annual meeting of the county medical society held at Jamestown on December 18: president, Dr. B. S. Custer, Fredonia; vice-president, Dr. C. Otto Lindbeck, Jamestown; secretary, Dr. Edgar Bieber, Dunkirk; and treasurer, Dr. F. Pfisterer, Dunkirk.—*Edgar Bieber, M.D., Secretary.*

Chemung County

The county medical society has voted to rename the *Elmira Tumor Clinic* in memory of its founder, Dr. Joseph S. Lewis, who died on January 21. The clinic meets each Wednesday at 11:00 A.M. at St. Joseph's Hospital for the study and diagnosis of malignant tumors.

Dutchess County

At the annual meeting in January, Dr. Edgar F. Powell, Fishkill, was elected president of the society. Others elected are: vice-president, Dr. E. A. Stoller; secretary-treasurer, Dr. John Rogers; associate secretary, Dr. L. W. Stoller; censors, Dr. Julius Haight, Dr. A. L. Peckham, Dr. G. S. Tabor, Dr. H. P. Carpenter, Dr. P. V. Buckley; delegate, Dr. Samuel Appel; alternate, Dr. Aaron Sobel.

Schedule of medical fees of at least \$2.00 for office calls and \$3.00 for house calls has been endorsed by the county society.

Erie County

The following officers were elected at the annual meeting held December 23.

President, Dr. Harvey P. Hoffman; first vice-president, Dr. Harold F. R. Brown; second vice-president, Dr. John D. Naples; secretary, Dr. Louise W. Beamis; and treasurer, Dr. Ralph M. DeGraff, all of Buffalo.

Chairman, Board of Censors, Dr. Eugene M. Sullivan; Chairman of Legislation, Dr. Joseph C. O'Gorman; Chairman of Public Health, Dr. John W. Kohl; Chairman of Economics, Dr. E. Dean Babbage; and Chairman of Membership, Dr. Charles R. Borzilleri, Jr.

Delegates, 1942 to 1943: Dr. Albert A. Gartner, Dr. Nelson W. Strohman, Dr. Carlton E. Wertz, and Dr. Herbert E. Wells.

Alternate delegates, 1942 to 1943: Dr. John T. Donovan, Dr. A. H. Aaron, Dr. Francis J. Butlak, and Dr. Milton A. Palmer.—*Louise W. Beamis, M.D., Secretary.*

At the meeting of the woman's auxiliary on January 27 which was held in the Hotel Statler, Buffalo, Dr. Harvey P. Hoffman, president, and Dr. Louise W. Beamis spoke.

On January 21 Dr. J. Bay Jacobs, Washington, D. C., spoke on "Management of Labor and Outcome in 800 Women with Borderline Pelves" at the Buffalo Academy of Medicine.

Franklin County

The Saranac Lake Medical Society had two excellent speakers for their meetings on January 21 and 28. On the twenty-first Dr. F. A. D. Alexander, director of anesthesia at Albany, spoke on "The Genesis of Respiration." On the twenty-eighth Dr. Norman Plummer, assistant professor of clinical medicine, Cornell University, discussed "Newer Chemotherapeutic Methods."

A dinner at the Elks' Club in honor of the guest speakers preceded the meetings. Around seventy members attended each session.

Herkimer County

At a medical staff meeting of the Little Falls Hospital on January 13 a schedule of increased fees was adopted.

The new fees, which became effective February 1, are \$2.00 for office calls, \$3.00 for home

calls between 8:00 A.M. and 10:00 P.M., and \$4.00 for home calls between the hours of 10:00 P.M. and 8:00 A.M. The customary extra charges will still apply for rural calls. The new schedule applies in Little Falls, Dolgeville, St. Johnsville, and other communities in which the physicians are members of the hospital staff.

Jefferson County

See page 373 for a schedule of lectures in the postgraduate course on sulfonamide therapy that is now being given for society members.

Kings County

At the regular meeting of the society on February 17 Dr. Philip Levine, Newark, New Jersey, will speak on "The Importance of Iso-Immunitization in the General Practice of Medicine." Dr. Foster Murray, Brooklyn, will also speak and will have as his subject "Primary Malignant Tumors of the Lungs."

In December the following county society officers were elected: president, William C. Meagher; president-elect, John J. Gainey; vice-president, Thomas B. Wood; secretary, Benjamin M. Bernstein; associate secretary, Eugene R. Marzullo; treasurer, Irwin E. Siris; associate treasurer, Harry Mandelbaum; and directing librarian, Jacques C. Rushmore.

Dr. J. M. Ravid will, for the third successive season, give a four-month course in gynecologic pathology at the Israel Zion Hospital in Brooklyn. This course is given under the auspices of the Joint Committee on Postgraduate Education of the Kings County Society and the Long Island College of Medicine. For further information apply to the Registrar, 1313 Bedford Avenue, Brooklyn.

Pan-American Medical Association.—Present-day headlines of the war in the Pacific and the Latin-American conferences prompted the Brooklyn and Long Island Chapter of the Pan-American Medical Association to arrange a most timely program for their next meeting on Thursday, February 26, at 9:00 P.M. at the Kings County Medical Society Building, Brooklyn.

The first speaker will be Mr. Russell Pierce, associate director of the Communications Division of the Office of the Coordinator of Inter-American Affairs. He will talk on intercontinental communications in regard to medicine, radio, news, motion pictures, and commerce. Mr. Pierce has spent many years in various South American countries.

The second address will be made by Dr. William S. Bainbridge, medical director, Captain, United States Naval Reserve, who will speak on "Pan-America—Today and Tomorrow." Dr. Bainbridge has recently returned from a six-month mission for our government, which took him to all the Central and South American republics and the important islands and bases in the Caribbean.

All physicians, their wives, and friends are cordially invited.

Livingston County

The 1942 Society officers are as follows: presi-

dent, Dr. A. J. Townsend, Dansville; vice-president, Dr. W. B. Turney, Avon; secretary-treasurer, Dr. G. E. Murphy, Mt. Morris; and censors, Dr. G. B. Manley, Geneseo, Dr. H. F. Hulbert, Dansville, Dr. W. T. Shanahan, Son-yea, Dr. G. E. Murphy, Mt. Morris, and Dr. C. Newton, Geneseo.—Gerald E. Murphy, M.D., Secretary.

Madison County

On February 17 at the Hotel Oneida, Oneida, at 8:30 P.M. Dr. Albert F. R. Andresen, professor of clinical medicine, Long Island College of Medicine, will deliver the final lecture of a postgraduate course arranged by Dr. O. W. H. Mitchell. His subject will be "Treatment of Gallbladder Disease."

Other lectures in this series included one on February 3 by Dr. Eugene R. Marzullo on "Practical Considerations of Blood Dyscrasias," and on February 10 Dr. M. B. Handelsman spoke on "Diabetes Mellitus—Its Modern Interpretation and Treatment."

Monroe County

"How to Keep Fit During the Present Emergency" was the subject of addresses delivered at a public meeting at the Rochester Academy of Medicine by Dr. G. Kirby Collier and Dr. William A. Sawyer on Sunday afternoon, January 25.

On January 30 Captain Lawrence Reilly of the Rochester Fire College spoke to the society members, their families, and friends on "Bombs, Gas, and Decontamination."

Captain Reilly received training at Edgewater Warfare College, Maryland, and his talk was highly informative and well illustrated by sound motion pictures.

Nassau County

"The relationship between the medical and dental professions is getting closer and closer because of new knowledge in both fields," said Dr. Charles W. Martin, president of the county society, at the annual joint dinner meeting of the medical society and the county dental society. The meeting was held on January 19 at the Garden City Hotel.

The president of the dental society is Dr. Herman Weinstein, Woodmere.

Dr. Russell L. Cecil of Cornell University Medical College and Dr. Daniel E. Ziskin, associate dentistry professor and chairman of the oral diagnosis division of the School of Dental Surgery at Columbia University, were among the speakers. Their topic was "The Relation of Systemic Diseases to Infections of the Mouth." Dr. Everett Jessup and Dr. Samuel Hoffman commented on the talks.

"In case of emergency arising from air raids or other attack it will be too late to collect and prepare the blood required for cases of severe injury and shock," says the *Nassau Medical News*. "Therefore, the hospitals in the county are endeavoring to prepare for all emergencies in advance." The society paper urges persons between the ages of 18 and 60 to inquire of their doctors how to go about donating blood.

TRAVEL MEDICINE

Messengerettes

War brings many changes—sooner or later we become adjusted to them. Yet, in Canada, in the third year of a war changes are still novelties, especially to visitors from this side of the border.

So the latest of these—the “Messengerettes.” With army, navy and air services depleting the delivery forces

of Canadian National Telegraphs, girls are being employed for day-time distribution of cables, telegrams and social messages.

While they do not whistle on the job, they otherwise possess the speed and efficiency of the boys they are replacing.

All Expense Vacations to Aid Defense

During these times of added pressure—the first duties of any airline is still to supply the nation with speedy, efficient transportation and to serve the many persons traveling in the interests of national defense.

Today, the air transport industry has added to its schedules and adjusted them to meet first the needs of those whose missions are urgent to our national defense and security. But there are many individuals in defense industries with additional work placed upon them requiring longer hours. Leisure time for them has been greatly reduced, and yet it is vital that the greatest

part of free time be conserved for proper relaxation.

With this in mind, the Canadian Colonial Airways has announced a series of all-expense winter sports tours which are dovetailed into its regular schedules to provide the maximum of pleasure with the shortest period of wasted time. These tours make it possible to be in the winter wonderland of the Laurentian Mountains in less than three hours after leaving New York.

They include visits of three to ten days, and serve as ideal vacations for people who can get away for only a weekend or a short winter vacation.

TERRACE HOUSE for ALCOHOLISM

A private sanatorium offering a specific treatment for alcoholism, formulated to relieve the craving for alcohol and with re-education working toward permanent abstinence. Homelike surroundings. Competent medical and nursing care. 16 miles from Buffalo.

Moderate rates—Enquiries invited

Physician in Charge

[Continued from page 378]

New York County

At the meeting of the society on January 26 Dr. Maximilian A. Ramirez announced, in his inaugural address, the organization of a physicians' war council by the county society. The council will attempt to organize and mobilize the professional forces in the county in a practical manner so as to cooperate effectively with the Director of Civilian Defense.

On the committee are Dr. Ramirez, chairman, Drs. Condict Cutler, Adolph DeSanctis, Ernst P. Boas, James Alexander Miller, and Herbert Wilcox.

Mr. Paul V. McNutt, Federal Security Administrator, addressed the physicians on War and Health. He said that nearly 25,000 physicians would be needed for an Army of 3,600,000 men, and he added that "our Army may double or, if necessary treble, that figure before it is through."

Dr. Alfred M. Hellman, retiring president, outlined the activities of the society for the past year.

Oneida County

Officers elected at the annual meeting on January 13 are: Dr. R. Sloan, president, Utica; Dr. B. F. Golly, vice-president, Rome; Dr. J. I. Farrell, secretary, Utica; Dr. W. F. Coxon, Jr., assistant secretary, Utica; Dr. H. D. MacFarland, treasurer, Utica; and Dr. T. Wood Clarke, librarian, Utica.

Censors are: Dr. F. T. Owens, chairman, Utica; Dr. J. B. Lawler, Vernon; Dr. A. F. Gaffney, Oriskany Falls; Dr. H. N. Squier, Utica; and Dr. L. E. Sprout, Rome.—*James I. Farrell, M.D., Secretary.*

See page 373 for postgraduate course.

Schuyler County

The 1942 officers are as follows: president, John William Burton, Mecklenburg; vice-president, Washington Merscher, Watkins Glen; secretary and treasurer, Oakley A. Allen, Watkins Glen; delegate, Joseph Youmans Roberts,

Watkins Glen; and alternate, Christian William Schmidt, Burdett.

Suffolk County

At the annual meeting of the society, held October 22, the following officers were elected for the year 1942: president, Dr. David Corcoran, Central Islip; first vice-president, Dr. Archie Baker, Lindenhurst; second vice-president, Dr. Frank Holmberg, Sag Harbor; secretary, Dr. Edwin P. Kolb, Holtsville; assistant secretary, Dr. Willetts W. Gardner, Patchogue; and treasurer, Dr. Grover A. Silliman, Sayville.

Censors are: Dr. Paul Nugent, Easthampton; Dr. Leon Barber, Patchogue; Dr. Louis Gerben, Islip; Dr. George Thompson, Southold; and Dr. Cyril Drysdale, Northport.

Delegates to the State Society are: Dr. John L. Sengstack, Huntington, and Dr. Coburn A. L. Campbell, Port Jefferson.

Delegate to Second District Branch is Dr. William H. Ross, Brentwood.—*Edwin P. Kolb, M.D., Secretary.*

Wyoming County

A joint meeting of the county society and the members of the staff of the Wyoming County Community Hospital was held on January 14 at the sanitarium. Dr. Mary Greene was hostess. Following dinner a meeting was held in the gymnasium with Dr. Paul A. Burgeson, president of the society, presiding.

Dr. W. D. Johnson, Batavia, as guest speaker began his talk by saying that instead of being a specialist who knew more and more about less and less, he had become a man who knew less and less about more and more!

Yates County

The officers of the county society for 1942 are: president, Dr. Allen Wheeler Holmes, Penn Yan; vice-president, Dr. Walter G. Hallstead, Penn Yan; secretary and treasurer, Dr. Robert F. Lewis, Penn Yan; delegate, Dr. Bernard S. Strait, Penn Yan; alternate, Dr. G. Howard Leader, Penn Yan.—*Robert F. Lewis, M.D., Secretary and Treasurer.*

Steamship Cruise This Spring?

Here's real Yankee ingenuity with Southern flavor. Never mind the war—for those who still love the tang of water travel, there is a cruise scheduled for the spring safe from submarines, mines and dive bombers.

It is a novel, springtime garden tour combining all the romance and lure of Old Man River plus a carefully planned itinerary with visits to interesting old mansions and southern gardens.

The steamer *Gordon C. Greene* is an old-time stern-wheel steamboat with comfortable cabin accommodations for about 200 passengers and a colored chef who is a master of Southern cooking.

The 15-day cruise starts from Cincinnati on March 7th. Going down stream there will be a number of interesting stops at famous river towns including Louisville, Evansville, Paducah and Memphis. On the morning of the fifth day, the steamboat will tie up at

Natchez, the famous cotton port of the Mississippi and two days will be devoted to enjoying the well known hospitality of that historic city.

The program of entertainment includes visits to many of the beautiful old homes and gardens for which the city is noted. There will be time to attend the Confederate Ball Tableaux and to enjoy a special program of Negro Spirituals in one of the nearby churches.

After Natchez, stops will be made at Vicksburg, Helena, Cairo, Paducah and back to Cincinnati.

The steamboat is ideally equipped for this springtime cruise. The main deck is glass-enclosed. There are sports decks open to the fresh air and sunshine where ping pong, shuffleboard and deck tennis may be enjoyed.

It is a cruise to be recommended—for a quiet, restful and pleasant vacation.

WEST HILL

West 252nd St. and Fieldston Road
Riverdale-on-Hudson, New York City

For nervous, mental, drug and alcoholic patients. The sanitarium is beautifully located in a private park of ten acres. Attractive cottages, scientifically air-conditioned. Modern facilities for shock treatment. Occupational therapy and recreational activities. Doctors may direct the treatment. Rates and illustrated booklet gladly sent on request.

Editorial

Rehabilitation of Rejected Selectees

"It is obvious," said Colonel Samuel J. Kopetzky, M.C., in an address delivered before the National Conference on Medical Service,¹ that "The army cannot use any man who cannot withstand the rigors of military service, nor does it want to induct any man who might become a liability, not alone to the government, but also to his community, to say nothing of an ensuing and continuing handicap to himself and his family for the remainder of his life.

"It is true enough there were many rejections. . . . In various quarters of our broad land there were some who seized upon the figures and made superficial deductions that, because of these figures, the health level of our people was 'appallingly low.' Such deductions were broadcast . . . in spite of the known fact that the health level of our people was higher than anywhere else in the world, with a mortality and morbidity record second to none.

"During the preparedness program (in the New York City area) percentages of rejections amounted to 23.64 per cent, this figure including absolute rejections at both the local board examining teams and the medical advisory board team, and also the army examining teams. There were an additional number . . . approximately 32 per cent, who were classified for limited service. . . ."

"It is found that with each added year the individual registrant shows more deficiencies. The figures are extremely interesting . . . 41.36 per cent of rejections in the age group under 25 years of age, 64.09 per cent of rejections in the age group 31 years and over . . . a differential which amounted to 22.73 per cent. . . . I have the right to deduce that the percentages of rejections in the new registration which is about to be undertaken, and which will embrace man power up to the end of the forty-fourth year, will be still larger, provided the physical standards for qualifying for full military service remain as they are now."

Undoubtedly, the rejection figures for the new group of selectees in the 20-45 age group will provoke new outbursts in the near future and proposals for legislative correctives to remedy the situation. Much talk is even now heard of a rehabilitation program. The purpose of such a program would be to make the unfit fit for the rigors of full military duty.

"It is interesting," says Colonel Kopetzky of the pilot experiment in rehabilitation conducted by him in New York City, "that 5.9 per cent of the rejectees were found being attended by practicing doctors and dentists or desiring to be referred to them. *The private practice of medicine and dentistry still enjoys public confidence.* Four per cent desired to be

¹ Rejected Selectees and Their Rehabilitation for Active Military Service, Chicago, February 15, 1942.

referred to public clinics mostly because they were financially handicapped Eight per cent of those who permitted a review of their physical examination forms absolutely refused to accept remedial therapy.

"Does it not seem wise," he asked, "to set up some machinery now whereby physically fit men at present serving in non-combat unit positions are relieved of these posts, and assigned to fighting units, and to fill the vacancies thus created by the induction of registrants now classified in 1-B? There is under way in the area of New York City an effort at rehabilitation of all 1-B men. Unhappily, most of these men cannot be made to meet the qualifications set for 1-A. They would still be poor combat material."

According to the *J.A.M.A.* of Janu-

ary 31, 1942, a rehabilitation program is to be initiated in Virginia and Maryland following somewhat along the lines of the pilot experiment in New York City, the pertinent results of which have been outlined by Colonel Kopetzky in his Chicago address. The statistical results will be awaited with much interest.

The purpose of any rehabilitation program should be to provide physically fit man power for the armed forces. Whether the problem should be approached and handled directly by the army or in some other manner seems open to debate. No reliable statistical data are yet available, to our knowledge, to indicate how successful any program could be in providing acceptable rehabilitated men for combat service under present rigid army physical requirements.

Waste of Man Power

At this time when every effort is being made to utilize the young, physically fit man power of the country for the armed forces, it is discouraging to contemplate the accident death toll in relation to age groups.

"One death in every three among youths and young men is the result of accident.¹ This striking fact may be set down as one penalty of our modern, mechanical way of life. For, while we have been eminently successful in reducing the death rate from disease, we have not been equally efficient in protecting ourselves against the hazard of accidental death, to which mechanical devices, and in particular the automobile, contribute so greatly. And so we find ourselves today with the startling ratio of 33 per cent of all deaths among young

males attributable to various types of accidents."

Whether the new restrictions on the manufacture of automobiles will alter this record seems debatable. At any rate, the annual toll is appalling. "At all ages combined, deaths by accident in the United States, 1937 to 1939, amounted, in round numbers, to 97,000 annually, and constituted 8.7 per cent of all deaths among males and 4.6 per cent among females."

Accidents apparently rank first as a cause of death among men over the broad range of ages 5 to 39. Some, at least, of this waste of man power is preventable, and it is to be hoped that the current necessity for conserving man power for the armed forces and for the all-important operations of industry will lend added impetus to the accident prevention movement.

To the Ladies!

Today, women all over the country are doing magnificent work in defense organizations. They deserve great credit. But, year in and year out, a group within our own state has been quietly making a valuable contribution both to organized medicine and to their own communities. We salute the Woman's Auxiliary to the Medical Society of the State of New York.

In adhering rigidly to the words of one member, "Remember always that we are just an auxiliary," they have sought no recognition, but their modesty has not obscured from us their significant work. A glance at the Auxiliary page in any issue of the JOURNAL reveals the scope and importance of their activities:

"Card party netted \$114 for Bundles for Britain."

"\$70 raised to purchase slide for underprivileged children's playground."

"Hygeia to be placed in the high schools of the city."

"3,000 hours of Red Cross work credited to the auxiliary."

"Committee appointed to assist tuberculosis project."

"Mental Health Institute sponsored last month."

"Two girl scout scholarships given."

"Toys bought for children in foster homes."

"Two Gatch beds to be presented to hospital."

"Health Forum sponsored by auxiliary a big success."

"Check sent to the Physicians' Home."

"Nutrition and First-Aid classes held."

"Speaker provided for Parent-Teachers Association."

It would be much easier to lengthen this list than to shorten it—for the reports include many other worthy causes and it is not possible to mention all of them. In addition to these activities, there is another contribution too valuable to be overlooked—namely, the friendliness created between physicians and families of physicians. One county writes: "We have decided to meet every month instead of the six times a year, for we feel that we will be more closely united not only as an auxiliary to the Medical Society but as *friends*."

At the annual meeting next month you will be able to say in person what we are now saying in print, but before then—perhaps even tonight across the dinner table—you might have an opportunity to salute one member of an organization that has won our unanimous admiration.

It isn't too early....

.... to make your reservations for the 1942 Annual Meeting: April 27-30, New York City. Headquarters will be at the Waldorf-Astoria Hotel. The program is one that you will *not* want to miss.

Correspondence

Rectal vs. Parenteral Administration of Sulfanilamide

To the Editor:

In a discussion of "The Treatment with Sulfonamide Drugs" (*New York State J. Med.* 42: 260, Feb. 1, 1942), Dr. Norman Plummer states that "following rectal instillation, all of the sulfonamide drugs are poorly absorbed. However, this applies to the sodium salts to a lesser degree. There seems to be little or no indication for the rectal use of the sulfonamide drugs, and this mode is to be discouraged." I cannot agree that "all of the sulfonamide drugs are poorly absorbed" for I have shown that sulfanilamide is well absorbed following the rectal administration (*Ann. Surg.* 112: 417, Sept., 1940; *Internat. Clin.*, in press). Strauss, Lowell, Taylor, and Finland (*Ann. Int. Med.* 14: 1360, Feb., 1941) and Wood (*Canad. M. A. J.* 44: 592, June, 1941) have confirmed the absorption of sulfanilamide after its rectal administration. The concentration of sulfanilamide in the blood fol-

lowing administration by rectum is sufficiently high to recommend this route when oral introduction is not possible.

Because of the foregoing and especially because of the present war conditions, I cannot see why "this mode (of administration) is to be discouraged." In hospitals situated in combat zones or in bombarded cities, the rectal administration of medication is definitely easier and simpler in execution and, therefore, preferable to the parenteral routes. Whereas, the subcutaneous or intravenous (parenteral) routes of administration of sulfanilamide demand sterile armamentarium, an aseptic technic, and the services of a physician, the rectal administration does not require asepsis and can be entrusted to a trained nurse (*Annotations, Lancel* 239: 656, Nov. 23, 1940).

February 2, 1942

Sincerely yours,
ROBERT TURELL, M.D.

DR. PLUMMER'S REPLY

To the Editor:

I am familiar with Dr. Robert Turell's study on the absorption of sulfanilamide from the large intestine and the rectum, and I appreciate his criticism of my remarks. However, I am not in full accord with him.

A number of investigators have shown that the sulfonamide drugs are absorbed chiefly from the small intestine and that the absorption is more rapid and more uniform from this region than from the colon. For example, Stead and Kunkel (*Am. J. M. Sc.* 199: 680, 1940) in a study on human subjects observed that when 300 cc. of 1 per cent sulfanilamide solution was injected into the duodenum through the Rehfuß tube, a level of 6 to 8 mg. per hundred cubic centimeters was obtained in the blood in ten to thirteen minutes. On the other hand, the same amount of drug when injected into the colon produced a blood level of from 2.4 to 4.0 mg. per hundred cubic centimeters in one and one-half hours. Such dissimilarities following oral

and rectal administration are much greater with sulfapyridine, sulfathiazole, and sulfadiazine than with sulfanilamide.

It is my impression that Dr. Turell has exaggerated the practicability of rectal therapy and the impracticability of the parenteral therapy. At the present time in most hospitals, the rectal administration of the sulfonamide drugs is not frequently used. This is the case because, in addition to the irregularities and uncertainties of absorption, there are the problems of retention of the drug. Parenteral treatment, on the other hand, has reached a point where it is usually a simple procedure and gives accurate and certain results. I agree with Dr. Turell regarding the changing times and that war conditions may require an alteration in our methods of treatment. Under the more usual conditions, however, I believe that the rectal use of the sulfonamide drugs is to be discouraged.

February 10, 1942

Yours sincerely,
NORMAN PLUMMER, M.D.

P. & A. SERVICE

PRINCIPLES UNDERLYING THE TREATMENT AND MANAGEMENT OF CORONARY DISEASE

FREDERICK A. WILLIUS, M.D., Rochester, Minnesota

FOR the intelligent treatment and management of a disease it is necessary to possess more than an acquaintance with the clinical features that permit its recognition. Unless knowledge regarding the disease is comprehensive it is impossible to expect the application of sound therapeutic measures, and under such circumstances empiricisms of a bygone era become revived. I am led to believe that such a therapeutic philosophy exists to a considerable degree in the present-day treatment of coronary disease. It is, therefore, extremely important that a conception be acquired which will permit the physician to appreciate the value, as well as the limitations, of therapeutic measures and their changing order of importance from case to case and also to realize the fact that nature is a great physician and that many times meddlesome, although well-intended, therapeutic intervention hinders or thwarts nature's efforts. It is not my intention to appear to be a therapeutic pessimist but rather to face the facts openly and attempt to appraise the problem as it confronts us today.

Coronary disease signifies arteriosclerosis of the coronary arteries. This process occurs variously in different patients and, as it progresses, displays multiple digressions that not only determine the resulting clinical phenomena of the disease but also profoundly influence the possible response to therapeutic measures and, therefore, dictate their indication or contraindication.

The efficiency of the heart is pre-eminently dependent on the adequacy of its blood supply, because this is directly the manner in which the respiration of the myocardium is maintained. Considerable variation occurs in the degree and extent of involvement of the coronary arteries among different patients. The main arteries and their larger tributaries are most commonly involved. The coronary arterioles remain remarkably free of pathologic alterations, even in diseases that are notoriously associated with arteriolar changes elsewhere in the body, such as so-called malignant hypertension.¹

Thus, the symptoms that the individual displays depend considerably on the extent, the degree, and the nature of the arterial involvement. The element of time is extremely important in the determination of a patient's destiny in the presence of coronary disease.

Blumgart, Schlesinger, and their associates^{1,2} and Smith³ of the Mayo Foundation have shown the beneficent effects of the development of collateral circulation of the myocardium, where single or multiple arterial tributaries have become completely or partially occluded. Under such circumstances a remarkably adequate myocardial nutrition may be maintained, the encompassing anastomosis acting as a by-pass in the region of the arterial occlusions. At times, new communications are surprisingly extensive, bridging the gap between main trunks and even resulting in new communications between branches of the right and the left ventricles. Such findings have been revealed in patients exhibiting no symptoms of coronary disease or whose symptoms were extremely attenuated.

In a discussion of the treatment and management of coronary disease it becomes necessary to consider its various clinical expressions. Under all circumstances it is of utmost importance to individualize the regimen to the needs of the patient and to avoid the undesirable consequences of routine treatment. Obviously, the first thought in the management of a patient is to limit the demands placed on the impaired heart, well within the threshold of its ability to respond. The adequate fulfillment of this premise may dictate a prolonged period of complete rest in bed in one case, whereas only moderate restriction of activities may be necessary in another. The physician must never overlook the fact that the patient who candidly confesses his subjective status knows better than anyone else the comfortable and, therefore, safe limits of his activity. Any degree of activity which recurrently causes insufficiency of the coronary circulation is hazardous and certainly defeats any attempt at therapy.

The anginal syndrome is the most common manifestation of coronary disease and is one that presents innumerable therapeutic ob-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Section on Cardiology, the Mayo Clinic.

stacles because its symptoms are paroxysmal in character, usually bearing a definite relationship to one or many factors capable of imposing increased demands on the heart, and because the patient who is not necessarily incapacitated refuses to observe the prescribed program. This syndrome is indicative of recurrent periods of myocardial anoxia which occur when demand exceeds supply, and the inescapable fact must be borne in mind that this signifies changes in the coronary arteries which are permanent and usually progressive and that no form of therapy available today is capable of altering the pathologic changes. In addition to structural arterial changes, the associated element of vascular spasm must be considered—not the spasm of the larger and diseased tributaries but of the arterioles of contiguous or neighboring vessels. This idea is sponsored by the sudden and dramatic termination of the painful seizures which, at times, is witnessed following the administration of such proved vasodilators as the nitrites and alcohol. However, cardiac economy, permitting an approximation of supply and demand, not only serves to foster comfort and safety but also enables the potential powers of the heart to establish collateral circulation.

When the myocardium is subjected to lower thresholds of oxygen for long periods or to marked deprivations of oxygen for shorter but recurrent periods, it responds by myofibrosis. This reaction may occur in localized areas related to the distribution of certain arteries, or it may become widely scattered as a diffuse process. Under these circumstances a stage is finally reached in which, even in spite of nature's attempt at establishment of collateral circulation, the functional capacity of the myocardium becomes impaired to such an extent that congestive heart failure becomes inevitable.

The nitrites and alcohol, judiciously employed, are of great value in supplementing the individualized regimen in the anginal syndrome. These agents, however, must not be used to extend the threshold of the patient's comfort, for such a procedure is fraught with great danger for the majority of patients. The xanthines, such as theophylline, theobromine, aminophylline, and the like, are extensively used, but their efficacy when administered orally is controversial. They are frequently administered in combination with sedative agents such as phenobarbital and sodium amytal, and it is probable that the resulting mild sedation is an impor-

tant influence in the improvement obtained. The simple expedient of prescribing sedative agents alone will tend to be rather convincing, for the advantages of lowered tension in the nervous system are acknowledged. Other factors of management occur, such as the judicious reduction of weight in obesity, the avoidance of overeating and imperfect mastication, the elimination of flatulent foods, rest periods after meals, regularity of bowel elimination, reduction in or discontinuation of tobacco, and the like.

It is a well-known fact that exertion in extremely cold weather more readily precipitates the anginal syndrome. Many patients experience their initial attacks under these conditions. This observation is dependent on a definite physiologic reaction. No doubt exists that the arterioles of the skin constrict when exposed to low temperature, as evidenced by blanching and actual reduction of the cutaneous temperature. Even in normal persons, exertion in cold weather tends to increase the depth and frequency of the respiratory excursions, with the result that the inspired air fails to reach body temperature when it enters the alveoli of the lungs. Thus, the arterial periphery of the lungs responds as does that of the skin, and vasoconstriction occurs and increases not only the load of the right side of the heart but also interferes with the prompt and adequate dissemination of oxygen into the pulmonary arteries. The simple expedient of covering the patient's nose and mouth with a porous muffler frequently will eliminate this factor.

I do not wish to discuss the various radical surgical procedures that have from time to time been recommended in the alleviation of the anginal syndrome because they have been extremely disappointing. Paravertebral nerve injection with absolute alcohol has some value in a limited group of cases in which all other measures fail and in which the painful seizures are frequently recurrent even under physical rest. This method of treatment is by no means universally successful and, at times, is complicated by intolerable neuritis. I shall not attempt to discuss the almost countless procedures and remedies that have come and gone, but, rather, I shall emphasize again the importance of realization of the pathologic changes responsible for the anginal syndrome and plead for a conservative and rational program of therapy.

Sudden obstruction of a coronary artery from one of several causes with ensuing acute infarction of the myocardium is no longer a

rare complication of coronary arteriosclerosis. It occurs most commonly as a result of thrombosis but may also result from hemorrhage into the wall of an arteriosclerotic artery, resulting in complete closure of the vessel at that point, or from the rupture of an intimal atherosclerotic abscess and the sudden discharge of lipid particulate matter into the lumen of the vessel, or less frequently from an embolus. The ensuing symptoms are largely dependent on the rapidity with which vascular closure occurs but are also dependent on the presence or absence of avenues of collateral circulation. When collateral circulation has been established, the final and frequently sudden vascular closure may permit the myocardium to escape acute infarction.

In the treatment of acute cardiac infarcts let us again be governed by realities. White and Patmos⁶ at the Mayo Clinic and, later, P. D. White and his coworkers³ have clearly demonstrated the sequences of acute myocardial infarcts. In general, these histopathologic studies showed that when death occurred within two to four hours regions of focal degeneration of the heart muscle were present and were associated with cloudiness, pyknosis of nuclei, diminution of the transverse striations, interstitial edema and congestion of the blood vessels. Infarcts from four hours' to five days' duration exhibited complete necrosis and acute inflammation. The necrotic portions were found to coalesce, and numerous polymorphonuclear leukocytes were present around the edges. A few lymphocytes, mononuclear leukocytes, and extravasated erythrocytes were present. The polymorphonuclear leukocytes first appeared within the adventitia of small vessels, and they gradually increased in number during the succeeding four or five days. In infarcts that were of two days' duration, phagocytosis of necrotic debris was well under way. Cellular changes, varying from hyaline to granular degeneration, were noted. Fibroblasts were observed occasionally at the margins of the necrotic portions of the infarcts after thirty-six hours, but they were not plentiful until the fifth day.

Infarcts from five to twenty-two days' duration, and even more, gave evidence of rapid disappearance of the inflammatory reaction and gradual replacement by connective tissue. Fibroblasts were particularly plentiful near newly formed blood vessels and, when the infarcts were of nine days' duration, they were abundant and the necrotic portions were greatly diminished. After twenty-two days,

regions of diffuse fibrosis were present. In infarcts from four to six months' duration, condensation and contraction of the fibrous scar were present; they represented complete healing. The prompt and adequate development of collateral circulation is without a doubt an important determinant in the prompt and uninterrupted healing of infarcts.

These facts clearly indicate the basic therapeutic premise for acute myocardial infarcts. The early recognition of the condition is of utmost importance, so that complete rest in bed can be promptly enforced. When complete rest is not imposed, serious and irreparable eventualities may ensue which include early congestive failure with or without the previous development of ventricular aneurysm.

In the majority of cases acute infarction of the myocardium is attended by severe and protracted pain, and it is important to afford the patient relief as soon as possible. Subcutaneous administration of an adequate dose of morphine sulfate ($\frac{1}{4}$ to $\frac{1}{2}$ grain or 0.016 to 0.032 Gm.) is generally accepted as the proper procedure and, if relief is not forthcoming within a reasonable period, an ounce (30 cc.) of whiskey taken by mouth frequently will result in dramatic relief. The vasodilating action of alcohol is well known and in this case, when attended by relief of pain, undoubtedly relieves associated spasm of regional small arteries and arterioles. When these procedures fail, the indication for rather continuous administration of high-tension oxygen becomes apparent.

A fundamental biologic phenomenon is concerned in this consideration, and it is one that appears on occasions to be overlooked—the process of healing. Throughout the body, regardless of whether the condition is a fractured bone, a cut or operative incision, a destructive inflammatory lesion, or a burn, repair is effected by the development of connective tissue and revascularization. Under the circumstances just enumerated it is possible, in most instances, completely to immobilize the parts, thus greatly enhancing the healing process. This advantage is denied in the healing of myocardial infarcts because the heart cannot be immobilized, but a considerable advantage can be gained by placing the patient at complete rest in bed, without any privileges of activity, for periods of at least six weeks or longer as the indications in the individual case may dictate. It is of great importance to attain both physical and mental relaxation after comfort has again been restored to the patient, and it is at this point

that well-tolerated sedative agents may be employed judiciously. When none of the modern preparations are well tolerated—which occasionally occurs, particularly among elderly patients—the careful administration of tincture of opium proves a blessing.

Unless complications intervene, such as significant disturbances in rhythm, recurrent pain, arterial emboli, pulmonary edema, or congestive heart failure, the role of the physician should be that of an alert but patient spectator. Only too often, well-intended but meddling therapy not only retards but endangers the patient's recovery. It is at this juncture that I wish to decry the use of digitalis, except in certain definite and, fortunately, uncommon situations. The physician who is cognizant of the true actions of digitalis will not be tempted to administer it, but the physician whose faith in this drug is empiric will not be dissuaded and may thereby directly contribute to the patient's delayed recovery or death. The prime indication for digitalis in coronary thrombosis is the advent of congestive heart failure, and even when that occurs I first resort to other measures, such as the administration of mercurial diuretic agents, hypertonic dextrose solution administered intravenously, and oxygen, before resorting to digitalis. Digitalis and heart disease, regardless of its nature, still seem to be inseparable and, although digitalis is one of the most important cardiac drugs in existence, it must, like all other drugs, be prescribed with understanding and intelligence.

Administration of quinidine sulfate at times is necessary, particularly in the control of ectopic rhythms, but it should not be rou-

tinely administered. It must be remembered that ventricular fibrillation is a terminal mechanism even in the unimpaired heart, and dramatic allegations embodying insistence on the routine use of this drug are no longer tenable.

When the time arrives for the patient to leave his bed, a crucial stage in the regimen confronts the physician. A cautious and flexible plan of gradual rehabilitation must be outlined, and it is in such circumstances that alert observation is of great importance. The gradual resumption of restricted activity must be effected without the production of symptoms. The time consumed obviously varies in different cases. The temperament of the patient and the nature of his work must determine his convalescence. Certain individuals may safely return to at least part-time duty in four or five months, whereas others may be obliged to remain away from work for a year or more or permanently. Here, again, the individualization of program becomes of paramount importance. In all cases, I believe, the patient must always adhere to reasonable restrictions. He must never revert to the natural abandon with which he carried himself before he had occlusion but should contentedly accept a *sang-froid* attitude of a protective philosophy.

CHANGE OF ADDRESS—WORKMEN'S COMPENSATION LAW

It is imperative that the office of the Compensation Medical Registrar of the Department of Labor, 80 Centre Street, New York City, and this office, be notified of all changes of address of physicians authorized to practice under the Workmen's Compensation Law. Such change of address, or the address of an additional office established by a physician, should be sent promptly so that our records and those of the Department of Labor may be complete. Physicians who enter the Service and give up their offices should be instructed to notify the Department of Labor and this office at once. If a substitute or locum tenens is appointed, it would be advisable to send this information to this office.

Secretaries of the county medical societies or chairmen of workmen's compensation boards or committees should bring to the attention of the membership of the Society, by all available avenues of publicity, the importance of sending this information to the proper authorities at once. This office and the Department of Labor are frequently called upon to provide lists of physicians at the request of employers, and it is important that our lists be up to date and accurate.

Will you kindly give this matter your attention?

—DAVID J. KALISKI, M.D.

FOLLOW-UP STUDIES IN CORONARY ARTERY OCCLUSION

I. Degree of Recovery, Symptoms, and Physical Signs

ARTHUR M. MASTER, M.D., SIMON DACK, M.D., and HARRY L. JAFFE, M.D.,
New York City

IN RECENT years a number of reports¹⁻³ on the follow-up course after acute coronary occlusion have shown that not only has the immediate prognosis of the acute attack improved but also the outlook for subsequent survival and rehabilitation is surprisingly good. As early as 1912 Herrick⁴ stated that "complete, that is, functionally complete, recovery ensues" in some instances, and at the present time complete recovery is commonly observed by those treating patients with this disease. In the first follow-up report on a large series of cases Conner and Holt¹ observed that a high percentage of patients remained in "good health" for at least one to five years. Numerous other authors⁵⁻¹⁹ have since reported a high incidence of survival for many years, as well as of complete functional recovery with little or no restriction of activity, particularly in the younger age groups.

In a previous investigation²⁰ we made the first detailed analysis of the degree of economic restitution in a series of 415 patients who had recovered from acute coronary occlusion, and we found that actually one-half returned to full- or part-time work within three to twelve months after discharge. The remaining patients were physically disabled by angina pectoris, dyspnea, or weakness. Complete clinical recovery was common, especially in patients under 40. These findings were corroborated by Segall.²¹ In the present study we are reporting in detail on the clinical status as determined by symptoms and physical examination in 202 of the above patients, insofar as they relate to cardiac function and prognosis.

Material

This study includes 202 patients treated in the Mount Sinai Hospital for acute coronary occlusion who survived the attack at least one year. The longest follow-up period was six years, the average being three years. Following discharge, the patients returned regularly for examination in the follow-up clinic at three- to twelve-month intervals. They were ques-

tioned with regard to the presence of chest pain, dyspnea, weakness, and the ability to walk, work, and carry on their daily activities. The occurrence of another attack of coronary occlusion or of heart failure was ascertained. In the physical examination attention was paid to the presence of dyspnea, orthopnea, cyanosis, signs of heart failure, the quality and intensity of the heart sounds, heart size, heart rate and rhythm, and blood pressure. In later reports we shall present the results of objective tests to determine the state of cardiac function, including the vital capacity, the two-step exercise tolerance test, the teleroentgenogram for the size and shape of the heart, the fluoroscopic and roentgenkymographic study of ventricular contraction, and the electrocardiogram. An attempt was made to correlate each test with the functional capacity of the patient and degree of clinical recovery.

The series consisted of 167 men and 35 women (Table 1), a ratio of 4.8:1. The incidence of men is slightly higher than the ratio of 3.4:1 during the acute attack.²² Sixty-seven patients were under 50 years, 90 were 50 to 59 years, and 45 were 60 years or over. This age distribution also differs slightly from that obtained during the acute stage of coronary occlusion,²² in that there were fewer patients over 60 and a greater number under 50 years. This may be attributed to the lower survival rate of the older patients during and after the acute attack and emphasizes the better prognosis in the younger age groups. Two-thirds of the patients had sustained their initial attack of occlusion; one-third had had two or three attacks prior to the follow-up period. The acute attack, personally observed by us in the hospital, had been mild in 45, moderately severe in 118, and severe in 39.

Results

A. *Degree of Clinical Recovery.*—The functional capacity of each patient was determined by his subjective response to effort. Two-fifths of the patients showed no, or only slight, restriction of physical activity—that is, angina pectoris, dyspnea, and fatigue were absent or mild in these patients (Table 2).

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Cardiographic Laboratory and the Medical Services, Mount Sinai Hospital.

TABLE 1.—AGE AND SEX DISTRIBUTION (202 CASES)

Age Group	No. of Cases
30-39	18
40-49	49
50-59	90
60-69	39
70-79	6
Sex	
Men	167
Women	35

TABLE 2.—DEGREE OF CLINICAL RECOVERY (202 CASES)

	No. of Cases	Per-centage
Functional Capacity*		
Unrestricted	34	17
Slightly restricted	47	23
Moderately restricted	57	28
Markedly restricted	64	32
Recovery†		
Good	63	31
Fair	56	28
Poor	83	41

* Determined by subjective response to effort.

† Summary of symptoms, physical examination, and objective tests.

TABLE 3.—INCIDENCE AND SEVERITY OF ANGINA PECTORIS (202 CASES)

	Prior to Attack	Following Attack
None	83 (41%)	78 (38.5%)
Mild	65 (32%)	44 (22%)
Moderate	52 } (26.5%)	56 } (39.5%)
Severe	2 }	24 }

TABLE 4.—COMPARISON OF ANGINA PECTORIS BEFORE AND AFTER ATTACK (202 CASES)

	Angina Pectoris After Attack	Present
53 Patients without previous angina pectoris	42 (51%)	41 (49%)
119 Patients with previous angina pectoris	36 (30%)	83 (70%)
	78	124

From a summary of the symptoms, physical examination, and several objective tests of cardiac function, the degree of recovery of each patient was classified as good, fair, or poor. In Table 2 it is seen that recovery was good in 31 per cent, poor in 41 per cent of the patients, and fair in the remainder. In other words, almost one-third of the patients recovered practically completely and were able to lead a fairly normal life. This is a high incidence in view of the fact that a good number of patients had been physically disabled by chronic coronary sclerosis or previous attacks of occlusion prior to the observed attack. The incidence of 31 per cent good recoveries in our series is surprisingly close to that reported by Palmer,¹⁶ who found that 29 per cent of his patients were able to lead fairly active lives. Padilla and Cossio¹⁰ also reported clinical cures in 29 per cent of cases

after six months. However, the observation of Cooksey¹² that 75 per cent of follow-up patients were asymptomatic appears too optimistic.

B. Symptoms.—Following recovery from the acute attack approximately two-thirds of the patients had complaints referable to the heart, such as chest pain, dyspnea, and weakness. The remaining third were symptom-free.

(1) *Angina Pectoris:* This was the most common symptom, being present in 61.5 per cent of the cases (Table 3), an incidence similar to that obtained by Palmer.¹⁶ In one-third of these patients the pain was mild and their ordinary activities were only slightly restricted, or not at all—the majority returned to work. The anginal syndrome following a coronary occlusion was often atypical, being vague in character, occurring in the left part of the chest, back, or shoulders, as well as substernally; not infrequently, it was unrelated to effort. The incidence of angina pectoris was approximately the same as it had been prior to the acute attack; this was due to the fact that an anginal syndrome often developed for the first time following the occlusion, whereas one that had been present previously not infrequently disappeared following recovery from the acute attack (Table 4). Thus, of the 83 patients who had never complained of chest pain, one-half continued to be free of pain and one-half developed angina pectoris following the attack. On the other hand, of the 119 patients who had had angina pectoris previously, 30 per cent were free of pain following recovery from the acute attack. When the pain persisted, it was generally increased in severity.

These observations, like those of other authors,^{14,16,23} emphasize that a coronary occlusion may initiate a chronic anginal syndrome or may be followed by complete cessation of previous angina pectoris. Eckerson, Roberts, and Howard²³ and Levy¹⁴ attributed the latter to the fact that following complete occlusion of a previously narrowed coronary artery the infarct is replaced by a scar that is physiologically inactive and does not contain nerve endings. This area, no longer sensitive to the effects of anoxemia, does not give rise to painful impulses. In the past it has been thought that disappearance of pain was related to the presence of a low or normal blood pressure following the attack.²⁴ Palmer,¹⁶ however, found no direct relation between the two, for in some of his patients anginal pain disappeared despite the return of hyperten-

sion. In our series, too, the blood pressure level did not appear to influence the presence or absence of pain. The incidence of hypertension both before and after the attack was practically the same in the group that lost their pain as in the group that continued to suffer from angina.

(2) *Dyspnea*: This symptom was almost as common as angina pectoris; it existed in 55 per cent of the cases (Table 5), particularly in patients with congestive heart failure. Not infrequently, it was the sole symptom of cardiac disability. Thus, 10 per cent of the patients suffered from dyspnea on exertion without precordial pain; in half of these there were no objective signs of heart failure.

(3) *Weakness*: A third common symptom was weakness, which was a significant complaint in 56 per cent of cases (Table 5). Occasionally, it was the only symptom of cardiac disability, but as a rule it was associated with angina or dyspnea.

C. Physical Signs.—(1) *Congestive Heart Failure*: Signs of chronic heart failure were present in 23 per cent of cases and were usually those of failure of the left ventricle (Table 6). They were of moderate or severe degree in only 7 per cent. Heart failure occurred in 13 per cent of the cases followed by Palmer¹⁶ and in 33 per cent of those followed by White and Bland.⁵ The incidence of heart failure is much greater during the acute attack; for example, we found it as high as 66 per cent.²² Thus, many patients with heart failure during the acute attack lose all evidence of failure following recovery. As a rule, those in whom signs of heart failure persisted had sustained a fairly severe acute attack, suggesting the occurrence of a large infarct. Practically all these patients were partially or completely disabled throughout the period of follow-up observation. In 6 per cent of the series, evidence of heart failure was present in the absence of angina pectoris.

Cyanosis occurred in 28 per cent of cases (Table 5). It was generally of mild or moderate degree. Although it was usually present in those with heart failure, it occasionally was observed in the absence of other signs of failure. A few patients presented a distinct ashen gray pallor instead of cyanosis.

(2) *Heart Sounds*: Diminution of the intensity of the heart sounds, particularly of the first sound, is a diagnostic sign during acute coronary occlusion. It was observed during the acute stage in two-thirds of our cases studied clinically²² (Table 7) and phonocardiographically.²² In the latter investigation

	During Attack	Follow-up
Normal heart sounds	13	38
Fair intensity and quality	59	69
Distant or poor quality	130	95
Gallop rhythm	63	17

it was found that the impairment of the first sound usually persisted throughout the patient's hospital stay. In the present study particular attention was paid to the character of the heart sounds at each follow-up examination. Almost one-half of the cases showed a persistent impairment of intensity of the heart sounds (Table 6). It is evident, therefore, that in the majority of instances, impaired heart sounds due to coronary occlusion were permanent or lasted for months or years. This emphasizes the diagnostic importance of studying the heart sounds in patients with coronary disease. Distinct impairment of the first apical sound in a subject over 40, particularly in the presence of a normal second sound, should raise the suspicion of previous coronary occlusion.

Gallop rhythm, an abnormality usually associated with a decompensated heart, was audible in 8.5 per cent of the cases as compared to an incidence of 31 per cent during the acute stages.²² This lower incidence during the follow-up period is undoubtedly associated with the lower incidence of heart failure during this period.

(3) *Heart Rate and Rhythm*: The vast majority of follow-up patients had a normal heart rate and rhythm (Table 8). Sinus bradycardia (60 beats per minute or less) occurred in 5 per cent and sinus tachycardia

TABLE 8.—HEART RATE AND RHYTHM (202 CASES)

(90 or more) in 15 per cent. The latter generally was present in patients with heart failure. Arrhythmias were rare (3 per cent) and consisted of chronic auricular fibrillation in 2 cases, paroxysmal auricular fibrillation in 3 cases and multiple ventricular premature beats in 1 case. A low incidence (3.5 per cent) was present also in Palmer's series of follow-up cases.¹⁶ On the other hand, the incidence during the acute stage of the attack was 14 per cent, exclusive of premature beats.²⁷ The rarity of cardiac irregularities is surprising in view of the large number of patients with severe coronary disease included in this series. It emphasizes the observation made previously²⁷ that cardiac irregularities that appear in acute coronary occlusion are rarely permanent and rarely recur following healing of the infarct. Since cardiac irregularities during the acute stage were commonly found in association with heart failure, the smaller incidence of severe heart failure following recovery from the attack may partly explain their infrequency during the follow-up period.

(4) *Blood Pressure:* Hypertension (150 mm. or more systolic and 90 mm. or more diastolic) was known to have been present in 60.4 per cent of the cases prior to the observed attack of coronary occlusion (Table 9), an incidence similar to that reported by us²² previously in

a larger series of cases. Following recovery from the attack the incidence of hypertension fell to 37.6 per cent; that is, following the attack the blood pressure failed to return to a hypertensive level in over one-third of hypertensive patients. Even when the blood pressure did rise to a hypertensive level, it often did not attain previous levels, for in the majority of cases the hypertension was slight or moderate. Readings above 200 mm. were less common than prior to the attack, as was noted by Allen.¹¹

In those cases in which the systolic blood pressure dropped to low levels during the acute attack it generally rose to 100 mm. or more within a few months following recovery. However, in 14 cases hypotension (less than 100 mm.) persisted for more than one year. The degree of clinical recovery in these cases did not seem to be less favorable than in those with higher blood pressure levels.

Allen¹¹ stated that the quicker the return of the blood pressure to normal or previous levels the better the prognosis and that the prognosis should be guarded in hypertensive patients whose blood pressure did not rise above a normal level following recovery. Similarly, Palmer^{16,23} found that when hypertension returned following the attack the patient fared somewhat better than nonhypertensives as to duration of life and recurrence of attacks. Gross and Engelberg²⁴ concluded that the subsequent blood pressure following coronary occlusion had no effect on longevity or on the occurrence and severity of heart failure. However, in our series hypertension seemed to have an adverse influence on clinical recovery. Although it did not increase the frequency and severity of angina pectoris, its incidence was distinctly greater in patients who subsequently developed heart failure (55 per cent) than in those without failure (32 per cent), doubtless due to the higher incidence of cardiac enlargement. While just as many extremely sick patients had a normal blood pressure as had hypertension, it is significant that hypertension was twice as common in patients who made a poor clinical recovery (46.4 per cent) as in those who made a good recovery (23.8 per cent). Conversely, only 20 per cent of the patients in whom hypertension returned following the attack made a good recovery, whereas 37.5 per cent of the nonhypertensive patients did so. However, hypertension did not influence the frequency of subsequent attacks of coronary occlusion, the latter occurring as frequently in nonhypertensive as hypertensive patients. This cor-

robates the observation of Palmer¹⁶ that a low or normal blood pressure does not protect against another attack of occlusion.

D. Subsequent Attacks.—A subsequent attack of acute coronary occlusion one year or more after recovery occurred in 44 of our patients (22 per cent), and acute heart failure not precipitated by another occlusion in 17 other patients (8.5 per cent) (Table 10). In 10 of the former and 2 of the latter, recovery from the first observed attack had been practically complete prior to the subsequent attack; nevertheless, another coronary occlusion or acute heart failure occurred. Generally, however, patients who sustain further attacks have recovered poorly or only partially from their preceding attack. Death occurred in 25 of the 61 patients who sustained another attack of occlusion or heart failure. Seven other patients died of extracardiac causes, such as a cerebrovascular accident. It should be remembered that only patients who survived at least one year after the acute attack have been included in this series. Patients who died prior to, or who were followed for less than, one year have not been included.

E. Return to Work.—It is now well established that a large number of patients who have recovered from coronary occlusion are able to return to work. Although Parkinson and Bedford⁷ in 1928 reported that 8 out of 66 patients recovered completely and went back to their ordinary work, no other exact statistics were available until the reports of Cooksey¹² and Master¹³ appeared in 1935. Three-fourths of the former's small series of 32 private patients and of Master's series of 71 private cases were able to resume their previous occupation or routine of life. The incidence of return to work is considerably lower, however, when hospital ward patients are considered, since they are usually sicker patients and their type of work is usually more arduous. Thus, only 29 per cent of Palmer's series¹⁶ of follow-up cases were able to resume unrestricted activity. More recently, we²⁰ reported on a much larger series, consisting of 185 private and 230 hospital follow-up patients. Fifty-seven per cent of the former and 50 per cent of the latter returned to full- or part-time work, the great majority within six months after recovery from the attack. The number returning to full-time work was distinctly greater in the private patients than in the hospital ward patients and in the younger age groups than in the older individuals. In Segall's²¹ series of 197 follow-up patients two-thirds resumed some form of

TABLE 11.—RETURN TO WORK (202 Cases)

	No. of Cases	Total	Percentage
Working		105	52
Full time	49		
Part time or light work	56		
Not working		97	48
Unable to work	88		
Retired	5		
Extracardiac factors	4		

work. He, too, emphasized the greater ability of the younger patients to return to work.

In the present series 52 per cent of the patients returned to work (Table 11), 24 per cent to full-time and 28 per cent to part-time or light work. Of the 97 patients who did not work, 88 were prevented by angina pectoris, dyspnea, or weakness and 4 by extracardiac complications, while 5 patients retired from work despite the absence of cardiac symptoms. The presence of mild angina pectoris or dyspnea, however, did not prevent return to work, since these occurred in almost one-half the working patients, particularly in laborers, manual workers, and housewives. Almost two-thirds of the patients under 50 years of age returned to work, the majority to full-time, while less than one-half of those over 60 returned to work, the majority to part-time or light work. As one would expect, the incidence also decreased with each succeeding attack of occlusion. Although as many laborers and manual workers returned to work as white collar and professional persons, a larger percentage of the latter were able to work full time. Almost one-half of those who resumed work did so within three months after discharge from the hospital; two-thirds, within six months.

These observations emphasize not only that clinical recovery following acute coronary occlusion may be fairly complete in one-third of the patients who recover from the attack but also that these patients may resume their former occupations or activities. A large percentage of patients who made only a fair clinical recovery also resumes full-time or part-time work, depending upon the degree of angina pectoris or dyspnea on effort. However, the latter may be no more severe than was suffered by these patients prior to the attack, despite the resumption of normal activity. The outlook for leading a fairly comfortable and active life following recovery from acute coronary occlusion is good.

Summary

1. A detailed follow-up study of the cardiac status, as determined by symptoms

and physical examination, has been made in a group of 202 patients who had recovered from an acute coronary occlusion one to six years previously.

2. Clinical recovery from the attack was good in one-third, poor in two-fifths, and fair in the remainder of the series. Two-fifths showed no or only slight restriction of physical activity.

3. Two-thirds of the patients complained of precordial pain, dyspnea, or fatigue and one-third had no symptoms of cardiac disability.

4. Angina pectoris occurred in three-fifths of the patients. Coronary occlusion may initiate an anginal syndrome or aggravate one previously present. On the other hand, pre-existing angina pectoris may disappear completely following the attack. The presence or absence of angina pectoris was not influenced by the level of the blood pressure.

5. Dyspnea, present in over half the patients, was occasionally the only symptoms of heart failure or cardiac disability.

6. Weakness was common but only rarely occurred in the absence of pain or dyspnea.

7. Chronic congestive heart failure was present in one-fourth the patients, a much lower incidence than during the attack and of a milder degree.

8. Persistent diminished amplitude of the heart sounds, particularly the first apical sound, was observed in about one-half the patients. This sign may be of diagnostic value in subjects over 40 suspected of coronary disease. Gallop rhythm, a sign of a failing heart, was not uncommon.

9. The heart rate and rhythm were normal in the great majority of patients. Paroxysmal or permanent auricular fibrillation occurred in only 5 patients. The rarity of arrhythmias in this series is in marked contrast to their frequency in the acute stage of coronary occlusion.

10. Hypertension, which had been present in two-thirds of the patients prior to the acute attack, returned or persisted in only one-third of the group following recovery. Although hypertension did not influence the frequency or severity of angina pectoris or the frequency of subsequent attacks, it was more common in those who developed heart failure and in those whose clinical recovery was poor.

11. One-half the patients resumed their former occupations, either full or part time. Inability to work was nearly always attributable to an anginal syndrome or heart failure. Mild angina pectoris or dyspnea, however, did not prevent return to work. The great

majority of patients who resumed work did so within six months after discharge from the hospital.

12. It is concluded that at least one-third of hospital ward patients who recover from acute coronary occlusion may lead a fairly active life with no, or only slight, restriction of ordinary activities.

Discussion

Dr. Louis H. Bauer, *Hempstead, New York* [This discussion also includes Dr. Willius' paper on page 409]—One rises to discuss papers by such authorities as Dr. Willius and Dr. Master with mixed emotions. He feels honored at being asked to discuss them but embarrassed that the completeness of presentation leaves little to discuss. There is left only the opportunity of reiterating some of the important points already brought out.

Dr. Master has given us a summary of various tests and their relationship to cardiac function after myocardial infarction. We have long needed some test of heart function which would be a reliable guide for increasing the activity of the patient. Dr. Master's paper ties in perfectly with that of Dr. Willius, who pleads for individualistic management, and these tests will help

us do just that. I was much interested in his two-step exercise test and am wondering if the Schneider index might not be used as a further test in the later stages of convalescence. When the test was first developed, Schneider felt that it was not a cardiac test in any way, but at that time we did not know so much about coronary disease as we do now and it is possible that this test also could be added to those proposed by Dr. Master.

I believe that too much stress cannot be laid on Dr. Willius' plea for individual treatment for the coronary patient. You hear much nowadays about the dangers of "mass treatment," and certainly in coronary disease we have a condition that—except for certain basic factors—should not be treated routinely. That this is true is brought out by Dr. Willius in his references to the pathologic background of these cases. One routine measure emphasized by Dr. Willius I do believe in, and that is a minimum of six weeks in bed regardless of the absence of symptoms following the development of infarction. Beyond that, routine management is to be avoided. Each patient should be guided along the path of convalescence in accordance with his reaction to increased activity. Gradual but steady increase of activity to the point of toleration should be encouraged. How far he can go depends on his individual response. The tests suggested by Dr. Master will help us assess this factor.

Many cases need no medication after the original morphine and oxygen. Sedatives are often advisable in the apprehensive or restless patient. I agree with Dr. Willius about quinidine. It is certainly most useful in certain cases, but I do not feel that there is any justification for giving quinidine routinely in every case the moment a diagnosis of infarction is made. I agree also that the use of the xanthines is a moot question. In fact, I would go even further than Dr. Willius and say that by mouth they are of no value whatsoever. Xanthines combined with sedative are more useful but I think there is no doubt that the sedative is the important factor. There is perhaps one exception and that is aminophyllin intravenously which is useful in a certain number of cases. I thoroughly agree as to his remarks on digitalis. Only rarely, if ever, is it necessary to use it. Minor symptoms of failure such as basal rales will appear in most cases, and they are not an indication for digitalis therapy. Bed rest alone will clear up a majority of the cases. In more marked congestive failure I believe diuretics, such as mercuripurin or salyrgan-theophylline, are safer and fully as satisfactory as digitalis. The myocardium in an infarction has already suffered a grave insult and it needs rest. Digitalis acts directly on the heart muscle and is contraindicated. A mercurial diuretic relieves the congestive signs without cardiac stimulation and is, therefore, to be preferred. In the later stages of myocardial in-

farction after healing is well advanced, there is less objection to digitalis, and many cases that have not shown signs of failure at the start may develop these signs as the patient becomes more active; then, digitalis may be used. In those cases of left ventricular failure near the onset of infarction, posture, bed rest, morphine, and oxygen are the ideal treatment. In these cases, too, mercurial diuretics may be used with benefit. While there may be cases in which the signs of failure are so marked that digitalis should be used early, they certainly are few and far between, and in my opinion it should never be used until other therapeutic measures have proved insufficient. I agree with Dr. Willius that digitalis is a most valuable drug, probably the most valuable drug in cardiac therapy and, were we limited to one drug, we would probably choose this. However, I believe also that it is the most abused drug in the pharmacopoeia. It is used when it should not be; it is not used when it should be and, when used, is often given in inadequate dosage.

It has been an honor and privilege to discuss these two papers by such well-known authorities, and I wish to express my appreciation for the opportunity of doing so.

Dr. R. M. Collie, *Schenectady, New York*—Just eighteen years ago, I recall hearing MacKenzie at St. Andrews Institute speak with skepticism of the value of any functional tests of the heart. The patient's general physical fitness, the amount of nervous fatigue, the incidence of pulmonary lesions, the patient's muscular development, and many other factors tend to disrupt the resultant findings as a reliable test of cardiac efficiency. However, I am sure that even MacKenzie, with all his supposed dogma, would be listening intently, were he here, to Dr. Master's findings.

My interest in these studies is more from a clinical standpoint and, unfortunately, not from that of the cardiologic laboratory. It is, necessarily, from an impressionistic attitude, rather than from the realistic, that I am able to speak.

In employing objective functional tests on these damaged hearts, we have tried to keep in mind the fact that angina pectoris, coronary occlusion, and myocardial infarction are probably different degrees of myocardial ischemia. They are different stages of nutritional deficiency of the heart. The relief from this deficiency is pretty much dependent upon the establishment of a coronary collateral circulation.

We have followed up a number of cases of coronary occlusion with objective procedures. This was done rather to determine the patient's cardiac fitness than to determine the comparative value of cardiac functional tests.

In reviewing some of the cases of a few years back, we were often surprised by the failure of follow-up electrocardiograms to show changes in cases of diagnosed myocardial infarction.

Now we know that they were probably cases of coronary failure without infarction.

As to the manner of production of these coronary injuries, a striking report was obtained from the medical department of the General Electric Company, from which come many of our cases. Here, in a plant which employs 25,000 workers daily, we find that during the past twenty years only 2 cases of myocardial infarction were reported which occurred while the worker was actively exerting. The many cases of coronary occlusion that I have seen which happened in this company have occurred outside the plant, while the patient was at rest—in other words, while coronary stasis was present.

In our follow-up work we believe that we have noted types or groups who take coronary insults quite differently.

First: the educated office man of, perhaps, 50—not physically fit, mentally fatigued, worried. Coronary narrowing was noted by frequent mild attacks of angina pectoris for a period

of years previous to the occlusion. In this group the morbidity was higher. By electrocardiogram and other tests on those who recovered, we found that the tests indicated but very slow improvement. Nevertheless, in these cases, the opportunity for the establishment of a collateral circulation was present.

Second: the mechanic who was physically fit—used his muscles every day. Usually, no previous attacks of angina or coronary failure were noted. His first coronary attack was crushing. If he recovered, his follow-up tests were better than the test obtained on the first group, and he commonly returned to work. All this resolves itself, seemingly, into the conclusion that the physically fit prevail. I know that they do not always prevail. Nevertheless, I have wondered if this second type, by the very nature of his physical exertion, did not develop a better coronary tree and was, therefore, able to establish more quickly an efficient collateral circulation at the time of urgent need.

HIGHWAYS TO HEALTH—"KEEP THE HOME FIRES BURNING" . . .

. . . is the title of an excellent series of radio talks on morale that is being given over the Columbia Broadcasting System from 4:15 to 4:30 P.M. on Thursdays. The New York Academy of Medicine, through its Committee on Medical Information, is sponsoring the series and the members of the subcommittee arranging the talks are Drs. S. Bernard Wortis, Fred P. Solley, Charles Diller Ryan, and Iago Galdston, secretary.

At a preliminary meeting it was agreed that:

a. The subject of Morale shall be treated from the constructive, positive, rather than from the negative aspect—to wit, little emphasis will be placed upon fears, anxieties, and the destructive aspects of war, while much attention will be devoted to those things which people can do in the motor sense to sustain emotional equilibrium and a competence to meet emergency situations.

b. There shall be advanced the basic thesis that war time does not so much create new emotional problems as it serves to intensify those that are common to civil life.

c. Noteworthy in the substance of the Morale talks will be such matters as will serve to counter-effect what has been aptly termed "The Four Horsemen of Morale Destruction"—to wit, Threats, Rumors, Fatigue, and Malnutrition.

d. The following specific concepts were recommended for inclusion in the talks:

1. Mental casualties result not so much from the threat of bodily harm as from disruption of the normal living processes.

2. The best antidote to panic is to engage the energies of people in communal and gregarious activities.

3. Those who express their anxieties in motor reactions can find release in activities of a social character.

4. Children tend to reflect the anxieties of their parents. The awareness of this by the parents will help them better to protect their children.

5. To children under 6 years of age, the home is the center of their emotional life, while to children under 11, school is the emotional pivot.

6. Food and warmth are all important in sustaining morale.

Following the first broadcast the announcer will summarize briefly the high points of the previous week's talk. At the conclusion of the talk, the theme song will be played and the announcer will give the name of the speaker and the title of the talk to be delivered the next week.

The program is as follows:

February 19	Dr. John L. Rice	Morale and Health
February 26	Dr. Thomas T. Mackie	Morale and the Diet
March 5	Dr. Foster Kennedy	Morale and the Adult
March 12	Mr. Lawrence K. Frank	Morale and the Family
March 19	Dr. William S. Langford	Morale and the Child
March 26	Dr. S. Bernard Wortis	A summary of the preceding five broadcasts

If the Columbia Broadcasting System can arrange to have these talks published in a small pamphlet, it will be distributed to those requesting copies, and an announcement to this effect will be made at each broadcast.

INTESTINAL OBSTRUCTION FROM THE PRACTITIONER'S POINT OF VIEW

W. OSLER ABBOTT, M.D., Philadelphia

FROM the standpoint of the practitioner of medicine, intestinal obstruction has always been a bugbear. He sees a patient with colicky abdominal pain. He has been taught that if it is intestinal obstruction the chance of recovery will grow less with every hour that passes before surgery is resorted to, but he also knows that if he calls for operation too early he will inevitably operate on many patients who have colic from other causes. The patient, too, believes that admission to a hospital for a blocked bowel will mean a laparotomy and urges his doctor to delay. In this dilemma how shall he proceed? The solution lies in a change in the point of view that has been slowly crystallizing in the last decade.

It has long been taught that obstruction may be accompanied by strangulation, in which event the hazard is increased, but, since the treatment always was immediate operation, the making of this diagnosis became, from the practitioner's standpoint, a rather academic procedure.

The developments of the last few years, however, have changed this, too. A patient with strangulation will succumb to infection spreading from the dead tissue, and it is simple cause and effect that unless the necrotic area is excised before it perforates a fatality will result. But what causes the fatality in the nonstrangulated case? Investigations aimed at the finding of a hypothetical "toxic substance" appearing in the obstructed patient have come to naught, but studies of the loss of essential substances from the patient have been most illuminating. Beginning with the early work of Hartwell and Hoguet¹ and their observations on salt and fluid and carrying on through the work of Haden and Orr,² Ochsner,³ Ravdin, Stengel, and Prushankin,⁴ and a host of others, it has become increasingly apparent that the high mortality rate is related to the depletion of nutritional essentials: fluids, electrolytes, proteins, calories, and vitamins. At the same time the

work of Wangenstein,⁵ Fine, Banks, Sears, and Hermanson,⁶ and others has shown that the mechanism of this change is simple distention, and we have been able to demonstrate that when distention is controlled and nutrition maintained the patient may continue in good condition almost indefinitely in spite of a complete obstruction of the gut. In a word, as has been frequently stated, death follows when strangulation goes unrelieved or when distention goes unreduced, but one must go further and say that the method of reducing the distention is of the utmost importance. When the old dictum of Sir Arbuthnot Lane that the sun should never be allowed to rise or to set on a case of intestinal obstruction was adhered to, the mortality for nonstrangulated cases was about 30 per cent or more. When nonsurgical methods of decompression are used, the mortality is about 10 per cent or less.⁸ Thus, one may say that in the face of the rapidly developing nutritional disorders of the obstructed patient it is as fatal to operate when one should wait as to wait when one should operate. The prompt diagnosis of strangulation is, therefore, no longer an academic problem but one of the most urgent importance.

What difference then, does all this make in the doctor's approach to his patient? In the first place, he may give his patient valid assurance that the diagnosis of intestinal obstruction will not necessarily condemn him to emergency surgery. Many patients with complete obstruction are returning from hospitals to a normal life without having been operated on. This point alone makes it far easier for the practitioner to obtain the patient's cooperation in going to a hospital while the obstruction is still recent or while the diagnosis is in doubt.

Having obtained the patient's consent to hospitalization, the next question is whether strangulation exists. The criteria have long been laid down in every standard textbook. It is the importance of the diagnosis rather than the manner of arriving at it which has changed. I shall stress three points, however, which are of great usefulness. First, with regard to the character of the pain, a patient with simple obstruction is doubled up by intense pain coinciding with waves of colic which

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

From the Gastro-Intestinal Section (Kinsey-Thomas Foundation) of the Medical Clinic, Hospital of the University of Pennsylvania. Aided by a grant from the Smith, Kline and French Laboratories.

are often audible without a stethoscope and not infrequently palpable or visible through the abdominal wall. With the passage of the wave he brightens up again and evinces little evidence of distress until the next colic grips him. The patient with strangulation, however, will have the same severe waves of pain, but between these waves he is not completely relieved by any means. This persistence of severe ischemic pain is characteristic. In the second place, strangulation is associated with far more superficial tenderness and there is a far greater tendency for the tenderness to be localized to some particular area of the abdominal wall than is the case in obstruction without strangulation. Finally, the waves of peristalsis which cause the pain in the absence of impaired blood supply can generally be inhibited by $\frac{1}{6}$ grain of morphine sulfate given subcutaneously, and with the cessation of contractions there is an end of colic, at least for the time being. The strangulated patient, on the other hand—as has long been taught by Dr. E. L. Eliason—is rarely given complete relief by a single dose of this magnitude.

If one decides that strangulation is present, surgery without further delay is still, and probably always will be, the proper course of action. From this point onward, therefore, I shall concern myself with those cases in which strangulation is felt to be absent and, since the aim of nonoperative treatment is the correction of the disturbance brought about by the obstruction, as well as of the obstruction itself, we must consider what these disturbances are.

The alternative to immediate operative intervention is decompression by intestinal intubation and the correction of nutritional defects by intravenous alimentation. The technic of passing a tube down the small intestine even to the colon has been described elsewhere. Suffice it to say that a special double-barreled tube having a thin rubber balloon at its tip must be used. The tube advances until it reaches the obstruction and remains there. Constant suction draws off intestinal content and the residue of the food. The doctor waits for one of two developments that depend largely on the nature of the lesion. The patient's metabolic state is brought into balance and then, when well prepared, he is either operated upon or else allowed to wait until the obstruction subsides. The frequency with which the latter result occurs is striking. The mechanism of the relief is related to the nature of obstructions in gen-

eral. They are frequently the result of three changes in the gut wall: first, an anatomic narrowing due to angulation, tumor growth, or fibrosis; second, a local inflammatory reaction; and, third, nutritional edema. The anatomic change is unaltered by conservative treatment, the local inflammation is relieved by sustained decompression of the proximal segment, and the hypoproteinemic edema is decreased by improved nutrition. The result will often be a disappearance of all evidence of obstruction.

The technic of correcting the deficiency must be considered under two heads: one, the handling of the acute condition when the patient is first admitted; later, his maintenance while waiting for subsidence of the obstructing process. Emphasis has long been laid on the use of intravenous saline. This is essential at the outset, and 3 to 5 L. are not infrequently needed in the first twenty-four hours. The advisability of adding 5 per cent glucose to this is well known. One must remember, however, that it is not the electrolyte content of the blood but its protein content that holds fluid in the vessels. Therefore, to prevent the saline from accumulating as edema fluid and thereby making a partial obstruction complete, the first material to be injected should be blood or plasma with the saline following it. After the first twenty-four hours the salt intake should be carefully considered. Since each liter of saline contains 9 Gm., 3 L. by vein becomes a salt intake far in excess of that which one could long tolerate by mouth, and the use of 5 per cent glucose in distilled water to make up part of the total fluid intake becomes helpful. With these solutions should also be given the less well-stored vitamins—viz., thiamin chloride, 10 to 20 mg. per day; ascorbic acid, 100 to 200 mg. per day; and nicotinic acid, 100 mg. per day. Such a regimen adjusted to the patient's individual needs will tide him over the acute stages of his disorder.

If it is an inflammatory obstruction such as may follow a late operation for rupture of the appendix or the repair of some traumatic perforation of the bowel, one will wish to maintain conservative treatment for days or weeks. The maintenance of the obstructed patient is therefore the next consideration. In all but the cases of high obstruction the feeding of a low residue diet is practical. Many obstructed patients live well on 1,200 to 1,500 calories per day in three to five feedings of lean beef and lamb, soup, eggs, cheese, rice, zwieback, melba toast, jellies, custards,

junkets, tea, coffee, sugar, butter, and cream to which is added, as the patient tolerates them, farina and puréed vegetables. The salt loss from the intestine is approximately 10 grains for every 100 cc. of drainage fluid and can be replaced by mouth on this basis.

This constitutes the basic procedure but, as the particular problems vary with the location of the lesion from the pylorus to the rectum, some special comment must be made. A high obstruction of the pylorus or duodenal cap infrequently presents diagnostic difficulties, for strangulation so rarely occurs there.

The nutritional aspect of these cases is characterized by the frequency of alkalosis from the loss of gastric juice. This is indicated clinically by the appearance of tetany and is forecast in the blood by a rising CO_2 level.

It was long taught that pyloric obstruction in the adult warranted immediate operation. Rasky³ has shown, however, the frequency with which one may bring about subsidence of the obstruction through conservative measures. Even where this does not result, the well-prepared patient is a far better surgical risk than the individual operated on when near a state of shock from incessant vomiting. Four or five days of gastric aspiration will, as a rule, enable one either to avoid operation or at least to feed a patient carefully until acute malnutrition is corrected and he is in condition to withstand gastric surgery.

In the small intestine the diagnosis of strangulation is less easy, but reference to the figures of McIver¹⁰ indicate the frequency with which strangulations in this region are palpable. The great majority result from hernias in the inguinal, femoral, or umbilical orifices or from hernias into old wounds. The residue includes a small handful of intussusceptions, an occasional volvulus or an intestinal herniation resulting from a congenital peritoneal fold or an artificial orifice resulting from a former operation or infection. Classification of obstructions without strangulation in this region includes not only the mechanical obstructions but also the so-called paralytic ileus, often resulting from lesions having no local connection with the digestive tract such as spinal injuries, and the self-limited inflammatory obstruction, resulting from local peritonitis. Here, however, refinements of diagnosis are, from the standpoint of procedure, still somewhat academic in that nonsurgical decompression remains the procedure of choice in all.

In each of these conditions the passage of a small intestinal tube either to the point of obstruction or, in the case of adynamic ileus, until clinical relief is obtained is the correct procedure. In jejunal obstructions aspiration draws off bile and pancreatic juices with their important ferment. The electrolyte content of the drainage, however, is chiefly made up of sodium chloride rather than hydrochloric acid; hence, alkalosis is less likely to complicate the problem than when the lesion is at the pylorus. Because of the large amounts of fluid that may at times collect unvomited in the distended gut, dehydration may be far greater than the volume of vomitus recovered suggests. If the obstruction is on an inflammatory basis and one wishes to decompress the gut for a week or ten days while waiting for the local inflammation to subside, the patient's ability to eat and drink while the tube recovers the residue is often of crucial value.

Obstructions of the colon are less apt to present a difficult diagnostic problem between strangulation and nonstrangulation than is the case in the small gut. The symptoms of volvulus are sufficiently urgent to leave little doubt in the matter. Slowly developing obstructions due to carcinoma, however, are relatively common, and the influence of nonsurgical decompression upon the handling of these cases requires a special word. The slow onset of symptoms invites an attempt at intubation, but from the technical standpoint it is far more difficult successfully to decompress the distended colon of a rectosigmoid obstruction than to cope with a blockage of the small gut lumen. Nevertheless, it is not infrequently possible to place the tip of a long intestinal tube in the cecum and by frequent irrigation to empty the colon proximal to the lesion.

Summary

Intestinal obstruction from the standpoint of the general practitioner is no longer a diagnosis that need carry with it the implication of an emergency operation. Means are available today for correcting and maintaining nutrition without utilizing the digestive tract; means are likewise available for emptying the gut proximal to an obstruction without incising it. As these changes have made the treatment of obstruction less routine they have made the prompt diagnosis of strangulation more urgent, for we are now coming to realize that it is almost as grave an error to perform an emergency operation on

an unprepared patient in the absence of strangulation as to delay surgery when the blood supply of the gut is in jeopardy. The surgery of nonstrangulated obstruction today, when it is necessary at all, should always be a procedure of election.

Discussion

Dr. Leon J. Leahy, *Buffalo, New York*—I feel that the method Dr. Abbott has just described is a great contribution to medical progress. It has been very well received throughout the surgical world, and the successful results following its use are indisputable evidence that it occupies an important place in the treatment of intestinal obstruction. This is especially true when one realizes that the mortality rate for intestinal obstruction in the not too far distant past was accepted to be in the vicinity of 30 per cent and that today, for example, reports of rather large groups of cases are made with the reduction of this figure to 5.9 per cent at the Presbyterian Hospital in New York and 9.5 per cent by Johnson and Penberthy in Detroit. In each of these series the Miller-Abbott tube was used with or without surgery.

In certain instances within the last ten years there has been a trend in surgery toward conservatism in the treatment of some conditions that were hitherto considered to be emergencies; for example, delay is advocated by certain excellent men in cases of early perforated appendicitis before localization has started. We are told that acute osteomyelitis, which was one of the real surgical emergencies, now is often treated expectantly until the soft tissues are invaded by abscess. A series of acutely perforated ulcers has been reported from Toronto, with a surprisingly low mortality rate, where

operation was delayed for varying periods of time until the patient was prepared for surgery. Today, a conservative treatment that can be used in many cases of intestinal obstruction has been brought to our attention. I state these facts because, in my opinion, this delayed treatment that I have mentioned requires the keenest type of surgical judgment based on experience, so that only the proper cases will be selected. I feel that it is something that must be learned and cannot be taught and, if possible, the errors should be made on the side of safety and the patient subjected to surgery when there is a doubt.

My experience with the Miller-Abbott tube has been limited, and perhaps for this reason we have encountered some delay in having the tube pass into the intestinal tract. This difficulty has possibly been one of the factors which has tended to discourage us from a more liberal use of this procedure. There are other factors, however, which have influenced this. We feel that it is hazardous to attempt to differentiate between the simple mechanical obstruction and the strangulated obstruction in early cases. I realize that the character of the pain, lack of tenderness, temperature, and leukocyte count all offer valuable help, but any of these is far from infallible. We also feel that strangulation may be superimposed upon a mechanical obstruction after the onset.

In 136 cases studied by McKittrick at the Massachusetts General Hospital it was shown that the duration of obstruction was the most important factor influencing the mortality rate, and he mentions 42 cases that were operated within twenty-four hours from the onset with no deaths. During the second twenty-four hours the mortality rate was approximately the same with or without delay; after forty-eight hours 33 per cent died when operation was done immediately, and 26 per cent died when there was a delay of six hours or more.

It is our custom to operate on the early cases immediately—by this I mean after hydration has been instituted and the chemical balance restored if these measures seem indicated. We also decompress the stomach and upper intestine by the Wangenstein method and leave the tube in place. In the later cases we feel that the use of the Miller-Abbott tube is indicated in selected cases and, in some instances when a marked improvement is noted and gas is passed by rectum, we continue this treatment. Occasionally, an operation is not necessary. We feel that a laparotomy is often indicated, regardless of marked improvement, because of the high incidence of recurrence.

FUNCTIONAL NERVOUS DISORDERS ASSOCIATED WITH WARFARE*

FOSTER KENNEDY, M.D., F.R.S.E., New York City

DURING the last war the term "shell shock" was employed in medical literature and, colloquially, also in the British Army to cover all cases of nervous instability occurring in warfare.

Under this heading were massed cases of amnesia, anergic stupor, sleeplessness, nightmare, mutism, functional blindness, tremors, palsies and, further, anxiety neuroses occurring not only under fighting strain but also in individuals still waiting for transport overseas. Further, the term became commonly used in newspaper journalism, whence it passed into common speech, always associated with a train of thought in the mind of the speaker, at once fearful and mysterious.

The general acceptance of this term and the apparent recognition of both medical officers and the public of a concrete, and above all quite novel, condition induced by experiences of unimaginable horror—the moving accidents of flood and field—had the obvious result of satisfying many a patient as to the propriety of his ailment; there was inevitably induced in him an easy rationalization of his illness, an easy self-justification in the very label tied to his tunic in the field ambulance, which, in all but the most redoubtable spirits, facilitated acceptance of his fate and to some extent inhibited effort on his own part toward his own cure.

Let me not be misunderstood: A conscious assumption of symptoms by soldiers in my experience—and in this I am completely supported by all other medical officers—was exceedingly rare; it was not rare for a man to go sick for a few hours to obtain a temporary alleviation of his lot, but seldom did one meet a man malingering with a view to discharge from the service.

Almost never were generalized psychoneuroses seen in soldiers suffering also from physical wounds.

It is not conceivable that of two men exposed in equal proximity to a heavy shell burst he who has no injury can have sustained a greater concussion than he who, for example, has also suffered a transverse lesion of the spinal cord; yet I never saw any sign of nerv-

ous instability—not to mention stupor, amnesia, functional abolition of the special senses or tic—in any individual who was dangerously wounded.

In his Chadwick lecture, Mott, speaking of the importance of the personal factor in determining the production of a neurosis, contrasted the case of a commercial traveler of nervous makeup who, after three days in the trenches, was returned to the base with tachycardia and tremor; who, six months later, had developed an almost complete functional paraplegia, with the calm and well-poised attitude, of another, an Australian soldier, suffering a spinal paraplegia, the result of a cord lesion inflicted by the explosion of an 8-inch shell 2 feet behind his dugout. Should we accept this comparison thoughtlessly we should miss what I believe to be one of the most important considerations in all this momentous matter. The comparison is false in that it compares two essentially unlike situations and leads us to the superficial and quite trite conclusion that a flabby, nervous fellow stands strain badly while a robust individual stands strain well.

Such a conclusion is, of course, true as far as it goes; but my experience makes me believe that had the little commercial traveler been shot in the spine his emotional apparatus would have remained under control and that had the Australian not been wounded in his narrow escape from destruction he might very well have come down the line with a mutism, generalized tremor, or some such expression of nervous breakdown.

Morale

The emotions of fear and pain constitute together our machinery of self-preservation; in most of us swathed in the cotton bandages of our civilized lives but little call is made on them. Constant exposure to imminent destruction in war produces, however, a tautness of the nervous system, a strain due to powerful excitement and, I would submit, to the organic stress induced by the mobilization of biologic instincts heretofore dormant. These instincts of self-preservation do not always, and perhaps not often, become conscious realizations. I mean that men, though in great danger, quite honestly may not feel

* Much of this paper was written in 1917 as "The Nature of Nervousness in Soldiers" and read in absentia before the American Neurological Association in 1918.

an unprepared patient in the absence of strangulation as to delay surgery when the blood supply of the gut is in jeopardy. The surgery of nonstrangulated obstruction today, when it is necessary at all, should always be a procedure of election.

In certain instances within the last ten years there has been a trend in surgery toward conservatism in the treatment of some conditions that were hitherto considered to be emergencies; for example, delay is advocated by certain excellent men in cases of early perforated appendicitis before localization has started. We are told that acute osteomyelitis, which was one of the real surgical emergencies, now is often treated expectantly until the soft tissues are invaded by abscess. A series of acutely perforated ulcers has been reported from Toronto, with a surprisingly low mortality rate, where

operation was delayed for varying periods of time until the patient was prepared for surgery. Today, a conservative treatment that can be used in many cases of intestinal obstruction has been brought to our attention. I state these facts because, in my opinion, this delayed treatment that I have mentioned requires the keenest type of surgical judgment based on experience, so that only the proper cases will be selected. I feel that it is something that must be learned and cannot be taught and, if possible, the errors should be made on the side of safety and the patient subjected to surgery when there is a doubt.

My experience with the Miller-Abbott tube has been limited, and perhaps for this reason we have encountered some delay in having the tube pass into the intestinal tract. This difficulty has possibly been one of the factors which has tended to discourage us from a more liberal use of this procedure. There are other factors, however, which have influenced this. We feel that it is hazardous to attempt to differentiate between the simple mechanical obstruction and the strangulated obstruction in early cases. I realize that the character of the pain, lack of tenderness, temperature, and leukocyte count all offer valuable help, but any of these is far from infallible. We also feel that strangulation may be superimposed upon a mechanical obstruction after the onset.

In 136 cases studied by McKittrick at the Massachusetts General Hospital it was shown that the duration of obstruction was the most important factor influencing the mortality rate, and he mentions 42 cases that were operated within twenty-four hours from the onset with no deaths. During the second twenty-four hours the mortality rate was approximately the same with or without delay; after forty-eight hours 33 per cent died when operation was done immediately, and 26 per cent died when there was a delay of six hours or more.

It is our custom to operate on the early cases immediately—by this I mean after hydration has been instituted and the chemical balance restored if these measures seem indicated. We also decompress the stomach and upper intestine by the Wangenstein method and leave the tube in place. In the later cases we feel that the use of the Miller-Abbott tube is indicated in selected cases and, in some instances when a marked improvement is noted and gas is passed by rectum, we continue this treatment. Occasionally, an operation is not necessary. We feel that a laparotomy is often indicated, regardless of marked improvement, because of the high incidence of recurrence.

weeks this experience recurred to his consciousness both by night in dreams and by day in dreaded interruptions to his normal train of thought, rendering him for that period incapable of duty, a prey to the paralyzing influences of both repulsion and fear.

In the beginning of this paper I said that I had not seen generalized psychoneuroses co-exist with somatic injury. Such, you may say, was not the opinion of all observers; but one must point out that such observers spoke of patients seen after transfer to England who on and near the field exhibited no evidences of nervous unrest. In other words, the neurotic symptoms in such cases developed after the elapse of an interval of days or weeks from the date of injury, which proves conclusively the psychogenic character of these symptoms and also, I fear, the uncomfortable fact that unwise suggestion from medical officers can do much to evolve and perpetuate somatic symptoms of psychic origin.

Further, the subject is confused by inadequate classification. I have used the term "generalized psychoneurosis" to include those patients whose inability "to carry on" was the result of their mental and emotional conflicts having been decided against their higher selves; whose morale had given way before the aggrandizement of their emotions of self-preservation; these were the tremblers, the amnesic, the disoriented, those with night and day dream deliriums, and the stuporous. The anxiety neuroses—a milder type of the same category—were most often developed in officers and resulted from prolonged strain and mental conflict rather than from a single external catastrophe.

Associated with the foregoing symptoms, or more often occurring independently, were various losses or perversions of localized function, usually classed as hysterical stigmas. These persisted after the patient had superficially resumed normal emotional control. On the whole, however, mutism, deafness, functional monoplegia, paraplegia, and functional spasms of the limbs were the result of localized suggestion rather than of generalized overwhelming of all the mental and emotional qualities, producing automatism and the temporary replacement of volitional by instinctive life.

By "localized suggestion" I mean some circumstances calculated to produce in a mind already apprehensive and strained a more or less fixed ideal of localized injury.

A case of paralysis due to local suggestion was that of a gunner wounded by a shell frag-

ment on the inner side of the left upper arm in May, 1915. The wound was slow in healing, and the arm was held by apparatus in the horizontal position for eight weeks to permit of irrigation and dressing. The wound healed with some adhesions around the ulnar nerve, causing a partial ulnar palsy and minor secondary adhesions in the shoulder joint through immobilization. From then on, he had a complete flaccid paralysis of the entire left upper extremity from the trapezius down to and including the intrinsic muscles of the hand. He was in a number of hospitals. More than eighteen months later he was discharged from the army with a total injury of the brachial plexus and, with satisfaction to himself, was finally pensioned. He was seen by me because he returned of his own accord to a London hospital to which I was temporarily posted to ask that the arm be amputated at the shoulder since it grievously interfered with his activities. No electrical assistance was invoked in this case, owing to the hypersensitiveness of the ulnar nerve through injury; but two conversations of explanation, persuasion, and tactful re-education—each of which, however, lasted for some two hours—restored complete range of movement to the arm and hand as far as was permitted by the organic disability.

It does not seem advisable to burden a communication of this kind with many case reports. That was done most fully by other observers. Indeed, the perversions and abrogations of function due, as has been said, to localized suggestion do not differ essentially from those seen in all neurologic hospitals of civil life. Naturally, the suggestions producing these conditions are of the most varied character, and identical disabilities may occur through a minor injury from being struck by flying earth, or as a result of a more serious injury from the diagnostic or verbal indiscretions of a medical officer.

Almost all injuries of the extremities, in my experience, are accompanied, for a short period at least, by a natural "defense immobilization" of the limb quite apart from any organic nerve injury. This is a natural reaction from pain in tired persons. A flesh wound of the upper arm, for instance, easily produces in such men the impression of inability to move the wrist and hand. And any doubts expressed by a physician as to whether or not, for example, a brachial plexus injury might not possibly account for the condition of the hand, sow the seeds of a fixed idea, which later may assume a sturdy growth.

afraid; their nervous systems may be said to be frightened, but their awareness knows no fear.

This submersion of such a powerful emotive force below the threshold of consciousness is due partly, perhaps, to the person's knowledge of the debilitating effects on his energies of the entrance of fear into his conscious life but much more, one feels sure, to the inhibitory influence of his morale. Now what is this thing we call morale? Is it not the expression in each soldier of his herd instinct, of his willingness to sacrifice himself for the benefit of his kind and for the ideals held in common by his countrymen and himself? It is a loyalty to his mates, to his officers, to his regiment, to his nation and, in the last instance, to the ideals of life for which his nation stands, and it is measured by his conscious willingness to suffer, his capacity for sacrifice in the common good. It is a quality born of the tribe, a product of gregariousness and so held socially in good repute. It is constantly expressed in thought; it is a real component of the soldier's conscious intellectual life. The shrinking from loss and the fear of death, on the other hand, are but rarely scrutinized in their realities; they are antisocial in trend and so are cast down, by good citizens, into the limbo of subconsciousness.

Perhaps I seem to you to have been wandering from my subject by these considerations; but one must try to discover something of the dynamic influences in our men, and I feel that a clue to the genesis of the neuroses is to be found in the antagonism, on the one hand, of the conscious emotions of loyalty and morale with their concomitant urge to self-sacrifice and, on the other hand, the more or less satisfactorily repressed instincts for the conservation of individual life.

The British soldier was not given overmuch to self-analysis and investigation of his emotional processes, but questionings carried out as tactfully as possible elicited in innumerable instances the information that being wounded subsequent to or during heavy shell fire is followed by a period of mental rest. And it would be strange were it otherwise. Such a man experiences a sense of an honorable relaxation of effort; he is, for the moment, quit of his obligations to others and freed from his fear of death. Further, his fate for the moment is decided and, despite his pain, he feels himself more fortunate than many of his fellows whom many times he has seen horribly destroyed. He waits for the stretcher-bearers to take him, and in most men there is a

conscious hope of a time of rest and home-coming.

In such experiences there are satisfied at once the man's biologic instinct for self-preservation and his social instinct of loyalty to his comrades and to that ideal of conduct which has been his buttress in times of agony and stress.

The converse situation, in which a soldier suffers the stupefaction and profound bewilderment consequent on exposure to heavy shell bursts *without* being wounded, is one in which the obligation to persevere still remains with him, together with a prospect of indefinite repetitions of like abominations, culminating, as after a time seems certain, in horrible mutilation or death. Under such circumstances the conscious morale and idealism of the man qualities, as has been suggested—of later growth than other instinctive processes—become drowned with the rising tide of his desire for life. The longing for safety, usually overborne by his conscious will, becomes overwhelmingly insistent and is expressed by the entire organism being given over to the phenomena of fear. The individual becomes in mind and body an automaton impelled by one instinct and one emotion; the mind, dazed and numbed, ceases to record impressions and is later found to be, for that period, amnesic. "Dumb" and "palsied by fright" are only popular expressions of the loss of special senses and the generalized tremors that ensue. The defensive reflexes, the dodging movements of the head, the sheltering movements of the arms, and the crouching movements of the body maintained for hours and days and, under improper influences, for weeks after the lapse of the exciting physical cause are an indication of the continued emotional tyranny under which he labors.

In different individuals this conquering of the nobler altruistic part of the man by the lower and more selfish instincts takes place in different ways. It may, and most often does, occur as the result of profound fright as has just been described or, after a long period of mental conflict and strain, there may come a situation carrying with it complexes of such emotional strength as to render almost helpless the will power to endure. Such a case was that of an officer of my acquaintance who, having borne the racking experiences of the landing and the trench fighting at Gallipoli, one day, jumping for what he took for solid ground, found himself—as he put it with a gesture of infinite disgust—"squelching thigh-deep in decomposed Turkish dead." For

ture of the problem with which we were, and are again, confronted. In doing so, only the psychologic aspects have been regarded, because these mental symptoms can be examined easily and treated successfully, though empirically, by rest, persuasion, re-education, and the restoration of self-confidence through suggestion and discipline. I have not been unmindful, however, of the physical changes which, accompanying violent emotional disturbances, result in alterations in the physiologic balance of the involuntary nervous system. We cannot yet know whether or not such reflex and secretory activities are the cause or the result of mental and emotional stress.

The collection of clinical and experimental data on such phenomena as, for instance, the functional disorders of cardiac rhythm following emotional tension (for example, for two days after being unpleasantly bombed I found my pulse rate irregular and uniformly over 100, though conscious of no mental strain once the danger was over) or dyspnea accompanied by increased absolute blood acidity. Similar cognate problems may in the future throw light on the association of integral activities of mind and body.

Such data, however, do little, as yet, to reveal the intrinsic nature of mind. To cope adequately with the wastage of health and of armies involved in this question, we must perforce deal with mental phenomena rather than with mind, and apply, with some empiricism, psychologic remedies to psychologic ills.

Much of what I have said was written a quarter a century ago. It was true then and is now. I would add a word on what I have heard from medical men and civilians and from official reports sent to Washington, put down in the light of my own experience.

Bombing from airplanes produces less neuroses than does shelling. This is natural for three reasons:

1. When shelled, you know the enemy has the range, and one has a nasty sensation of being personally applied for.

2. Bombing is a "catch as catch can" affair; it seems like a bad thunderstorm; one helpfully remembers that "lightning never strikes twice in the same place"; there are intervals of quiet.

3. There is nowhere to go that is safe.

It was the same in the last war; neuroses did not come out of bad air raids, and there were some raids just as bad in point of dead and wounded as there are now. At that time there was less defense against them.

The neuroses now come more from the petty bothers of a disturbed life, such as lack of sleep and broken plans, and it would seem that in point of endurance of these troubles the women do better than the men. After great department stores had been heavily bombed but were still able to continue business, only one-half of 1 per cent of employees, mostly women, failed to report next day for work.

In this war it is found that conversion hysteria, such as a hysterical palsy, cures anxiety just as a wound cures a strained emotional state; but there aren't many cases of conversion hysteria. Gordon Holmes writes to me that the rather elaborate neuropsychiatric centers prepared before the war and during the comparatively quiet first year have been almost unused. The neurologic center equipped for the use of the Royal Air Force has never been opened, despite the strain of the Battle of Britain in the second six months of 1940. This is not to say that pilots of the R.A.F. suffer no nervous symptoms. They will have an anxiety state if they are not sure of their equipment, if they have machine guns only and no cannon, if they lack confidence in their ground crew, should they be uncertain of the integrity of their landing gear, should they lack the certainty of being warned by their home airfield early enough that it has become covered with fog since they left so that they may be routed to some other landing field that is clear. Mutual regard, mutual integrity, mutual confidence, loyalty unto death in all, and the knowledge that there is no possible escape—there, then, is little failure in nervous strength. Fliers after 1,000-mile flights in bad weather conditions, heavily "flacked," who perhaps have had to bring down a wounded gunner to safety, may, after arrival, pass into apparent stupor and mutism and for twenty-four hours may be completely immobile in bed except for trembling of a constant character, but these officers are often able to take to the air again in thirty-six hours after that period. It would seem that a flier who begins to sit apart broodingly, is edgy, snappish, and critically harsh of his seniors, should not again be sent up until he is rested.

In the last war I found myself for about ten months the sole judge of whether flying officers who said they were unable to fly that day should or should not be sent up. I lacked the education or knowledge by which to determine this issue. I knew from my own experience that under strain there occurs ob-

Psychologic Character of the Problem

This brings us to the vital factor underlying the successful treatment of all somatic expressions of psychic unrest. In a word, it is *accurate technical knowledge*. The power to make a careful physical examination, to weigh evidence with precision and, thereby, to attain correct diagnosis, is the *only* power that will give the medical officer sufficient self-confidence to be able to communicate healing to his patient.

Time and again I have seen a half doubt in diagnosis prevent a coming together of the minds of physician and patient. If the medical officer is not entirely certain of the nature of the condition under review, his ability to cure it will be inhibited by a suspicion of the existence either of an organic nerve lesion, on the one hand, or of a conscious malingering on the other.

In short, functional motor and sensory palsies and functional perversions of the special senses are created by suggestion directed toward the affected faculty or member and are susceptible of cure by like means and only by like means. To differentiate them easily and rapidly from similarly appearing organic conditions is the first and most important step in their treatment and one which, having been taken with firmness and accuracy, will confer on the medical officer the self-confidence and authority to exorcise the system of false ideas that has been the immediate cause of the condition.

I say "immediate cause," for in these cases due to localized suggestion there is undoubted evidence of the presence and effects of the same mental conflict, the strain of which produces in other men states of anxiety or other generalized psychoneuroses still more incapacitating for military duty.

Soldiers since the beginning of armies have been clear-eyed in their knowledge of the conflicts of instincts. They have not, of course, dealt in the turgid phrases of our schools, but they have felt surely the binding qualities of the herd and have seen in them the only emotive force fit to overcome in their men their fear of death. They, too, have known that the cement of the herd is the suggestibility of man and that their instrument of suggestion is called "discipline."

So in this matter the medical officer has an onerous and difficult task.* He acts both for

the state and for the soldier, and to deal fairly with both clients it is vital that he should appreciate the truly psychologic character of the problem with which he has to wrestle. Only by so doing can he free his patient of his symptoms and, what is still more important, protect the armies from the contagion of suggestion so apt to sweep through such closely coordinated communities, each individual of which is exposed to identical causative conditions.

The essential feature of these ailments having been grasped, they must be classified and christened. In the beginning of this paper it was pointed out how the term "shell shock," founded on false premises, not only served to suggest an incorrect etiology but also, by its pitiful and romantic sound, tended to perpetuate symptoms and to excite no determination in the mind of the sufferer to recover his control or, in the fighting man, still to endure. So far was it from making an appeal to conscience or to discipline that it stifled both and stultified effort toward cure.

The name was a mistake: we must hear it no more. Let us have instead a true term that will be neither a compromise nor a technicality unintelligible to the mind of the soldier.

Hysteria is unsuitable, in that its significance to laymen and physicians is not identical; nor does it embrace, for instance, such conditions as the anxiety neuroses. The simple word, "nervousness," comprises all the neurotic manifestations seen in war. It furnishes an appeal to the sense of discipline in the armies, and further promotes the growth of a public opinion, both military and civil, which would be of greatest prophylactic and therapeutic power.

This diagnosis should continue to be divided into nervousness (sick) and nervousness (wounded) as now obtains, according to the external conditions to which the man was exposed at the time of the breakdown. This change in military nomenclature would make clear to both soldiers and civilians that such diagnoses need not necessarily be followed by a return to home or to the base, and would clearly indicate the propriety of dealing with such cases diagnostically and therapeutically in rest camps, and especially work camps, in front areas and on the lines of communication.

What has been written here is simply an attempt to set down in general terms the na-

* Indeed the two officers in a battalion chiefly responsible for the morale of that battalion, are the Colonel and the Medical Officer. The M.O. ought to be the "liaison officer" between the men and the other officers. He usually

censors the battalion letters; he ought to know the men by name; he must, on occasion, go anywhere the men go; he must have fortitude and must know how to temper it with kindness and firmness. If he can conquer fear himself, the men will also.

SERODIAGNOSIS OF TRICHINOSIS BY MEANS OF COMPLEMENT FIXATION

ERNEST WITEBSKY, M.D., PHILIP WELS, M.D., and ANNE HEIDE, Buffalo, New York

ACID hydrolyzed extracts of larvae of *Trichinella spiralis* were first prepared by Bachman^{1,2,3} and used as antigen for skin and precipitation tests for the diagnosis of trichinosis. Since Bachman's investigations, interest in the laboratory diagnosis of trichinosis has become general. Hunter;⁴ Augustine and Theiler;⁵ McCoy, Miller, and Friedländer;⁶ Bachman, Molina, and Gonzalez;⁷ Trawinski;⁸ Bozicevich;⁹ and others contributed greatly to the knowledge accumulated so far as to the technics of antigen preparation, as well as interpretation of the reactions obtained.

The complement fixation test in trichinosis has been employed as early as 1911 by Ströbel,¹⁰ Romanovitch,¹¹ and again by Bachman and Menendez¹² mainly in animal infestations. To our knowledge the results did not stimulate any further interest in the development of a complement fixation test. For that reason and because there could be no question about the presence of antibodies in the blood serum in infestations with *T. spiralis*, we tried to develop a complement fixation test that could be applied for the serodiagnosis of human trichinosis.

Material

Serums from infested human beings, as well as from experimentally infested rabbits, were examined. The rabbits were infested by feeding them infested rats in the following way: In the first group the rabbits were infested by forcing a piece of diaphragm of infested rats down their throats, followed by water given with a dropper. They were held on their backs until we were sure that they had swallowed the material. The animals were reinfested three weeks later with part of an infested diaphragm as described above. The rabbits in the second group were stomach-tubed with larvae obtained as described in the next paragraph. Later on, they were again reinfested with a part of an infested diaphragm. Altogether, twelve rabbits were infested.

Trichinella larvae were obtained in the following way: Rats were infested with trichinous meat and killed five to six weeks after infestation. The rats were skinned and eviscerated, and the remainder of the carcass was minced in a meat grinder. The ground meat was placed in a funnel over a perforated porcelain plate. Digestive fluid was prepared by adding pepsin and hydrochloric acid to tap water, and the apparatus containing the material was placed in the incubator at 37 C. for about one day. The larvae were liberated from their cysts by the digestive fluid. They fell through the stem of the funnel into a small centrifuge tube that was attached by a piece of rubber tubing. The larvae were then washed with saline solution and dried in a desiccator. The method described was originated by Hobmaier and Meyer.¹³ As to the details of the method used, we refer to the publication by Bozicevich⁹ from the Public Health Service in Washington.

Experimental

Watery extracts were prepared from the dried and powdered larvae. Fifty parts of alkaline saline solution (pH 8.0) were added to one part of the dried powder. The mixture was extracted at room temperature for three to four hours, during which time it was thoroughly shaken several times. Extraction was continued in the icebox overnight. The material was then spun down. The supernatant fluid was decanted and boiled for fifteen minutes in a boiling water bath. A fairly large precipitate was formed which was thoroughly spun down for one hour in the centrifuge. The clear supernatant fluid was used as the antigen in our experiments.

The antigen was boiled because of occasional nonspecific reactions that occurred when unboiled material was used in the complement fixation test. Boiled antigen had been employed previously by other experimenters, but it had been discarded because it was their impression that there was a loss of activity. According to our experience, boiling decreases the activity of the antigen in test-tube experiments only slightly. The

sessional thinking about one's own destruction. So, after a physical examination I would ask these officers if, when they were flying, they ever saw themselves in their mind's eye crash. If they seemed to understand what I was talking about, I never let them fly; and they usually did understand, for they were honest men. Imagination, self-consciousness, fatigued obsessional thinking do not go with the orderly conditioned reflexes needed for good flying.

It would seem, too, that this time civilian neuroses are sometimes *cured* by the real experience of war, and validity replaces invalidism. We know in civil life that peptic and duodenal ulcers come as a result of prolonged emotional strain. It is so also in war. Bombing makes for unpunctuality in meals, as well as uncertainty of survival. This dual irregularity has made a great increase in England, among soldiers and civilians, of gastric and duodenal ulcer. I gather from British reports that in bad times common horse sense and good social welfare work help more than do the doctors of the mind. Also that the great majority of civilians would rather be bombed in town than bored in the

country; and that perhaps the most important weapon against nervous breakdown in war is a sense of unity with your immediate group. It is vital that children before 11 years of age have a sense of unity in their family and that after 11 they have a sense of unity in their school. Disunion in either of these groups causes uncertainty of action in the person who feels uncertain, and at the end of all, if society is even temporarily disrupted, childish or adolescent delinquency can be traced back invariably to the removal of parental control. The herd instinct has been described as important in helping each individual do his task. We know from this war that each man's social reputation is important to himself. The small town man is always afraid of the neighbors' opinion. In Britain it has never been "good form" to show overmuch emotion; this is a precious asset when bombs are falling. *Of course*, each man is afraid, but, if he is never allowed to show fear and if he shows little fear to others, panic is not spread. Discipline to be perfect must be within—only in lesser terms from without.

410 East 57th Street

FELLOWSHIPS IN PSYCHIATRY

The National Committee for Mental Hygiene announces a limited number of fellowships for training in extramural and child psychiatry. Selected fellows will spend one or two years in a designated clinic, the term and plan of the fellowship to be determined by the peculiar needs of the applicant. Candidates should have had at least a general internship and two years of psychiatry in an approved mental hospital service in addition to other qualities fitting them for extramural service. The stipends vary slightly with location and status of the fellow but in general range between \$2,000 and \$2,600. Additional information should be obtained from Dr. Milton E. Kirkpatrick, National Committee for Mental Hygiene, 1790 Broadway. New York.

SPARKPROOF SHOES FOR TROOPS

Sparkproof shoes are among the latest types of footwear being tested by the Army, says the J.A.M.A. for November 1. The new shoes are designed for soldiers who dispense gasoline and other inflammable materials, particularly in the Armored Force where a spark may be disastrous.

Vulcanized fiber instead of metal is being used for washers in the heels of these new shoes, and the nails are made of a nonsparking metal. Shoes made according to this new design are being given a thorough workout by soldiers of a gasoline and oil battalion in the Armored Force. If they prove satisfactory, all soldiers who perform duties in which a spark may be dangerous will be provided with these sparkproof shoes.

P. & S. ALUMNI DINNER

The annual American Medical Association dinner of the Alumni of the College of Physicians and Surgeons, Columbia University, will be held at the Hotel Claridge in Atlantic City, New Jersey, on Wednesday, June 10, 1942, at 7:00 P.M. The local committee in charge will be Dr. Robert B. Durham, '28, chairman, Dr. John S. Irvin, '12, and Dr. Clifford K. Murray, '25.

MATHEMATICALLY SPEAKING

A dusky son of Alabama was busily engaged in a cootie hunt. When asked by the sergeant what he was doing, he replied:

"I'se huntin' for dem 'rithmetic bugs."

"Why do you call them arithmetic bugs?"

"'Cause dey add to da misery, dey subtracts from my pleasure, dey divides ma attention, and dey multiplies like de debil."

* Read after twenty-five minutes.

† Read after ninety minutes.

was used. This might account for the slight reaction obtained with normal rabbit serum. We had an opportunity to follow the patient up to April, 1941, and to take blood specimens from her at different intervals. The serum specimens were frozen in order to keep them over this long period of time. The following experiment shows the comparison in titer of different specimens taken from the patient at intervals of one to two months, respectively.

Decreasing amounts of inactivated patient serum, volume 0.1 cc., were mixed with a 1:500 dilution of the antigen and 0.1 cc. of a 1:20 dilution of guinea-pig serum. After incubation for one hour at 37 C., 0.2 cc. of sensitized sheep cells were added. The reading was taken after twenty-five minutes' incubation at 37 C., after which time the serum and extract controls had dissolved completely.

A steady decrease from an original high in the antibody titer of the patient can be recognized from Table 2. This high apparently was reached one to three months after infestation. It should be stated that the last blood examination of the patient was carried out on April 9, 1941, fourteen months after

infestation. The serum still gave a positive reaction.

A blood specimen from a second patient (R. I.) with trichinosis was obtained two weeks after infestation, according to the story of the patient. The diagnosis had been established by biopsy. When examined by means of the precipitation test the serum gave a slight precipitation after four hours' standing at room temperature in an antigen dilution of 1:50. It should be mentioned in this connection, however, that precipitation tests of that type as a whole should not be kept for such a long time but should be read earlier because of the possible interference of nonspecific reactions. The results obtained with the complement fixation also were irregular. Therefore, we tried to increase the sensitivity of the complement fixation test. This was accomplished in the following way:

Decreasing dilutions of inactivated serum, volume 0.1 cc., were mixed with 0.1 cc. of the 1:2,000 diluted trichinella antigen and 0.1 cc. of a 1:20 dilution of guinea-pig serum. The experiment was set up in three parts (see Table 3). Part 1 was incubated for one hour at 37 C.; Part 2 was kept for two hours in the icebox and then transferred to the in-

this patient on March 1, 1940, and was examined as to the presence of antibodies in the serum by means of precipitation and complement fixation. Table 1 shows the results of those tests.

The experiment itself was carried out in two parts—Part 1, a precipitation test; Part 2, a complement fixation test. The following serums were used in both parts of the experiment: (1) serum of rabbit No. 137 infested with *T. spiralis* for three months; (2) serum of patient, A. K.—specimen taken March 1, 1940; (3) normal rabbit serum; (4) normal human serum.

The precipitation test was set up in the following way: To decreasing dilutions of the antigen, volume 0.05 cc., were added 0.05 cc. of undiluted active serum. The tubes were shaken thoroughly and kept in the ice-box overnight because the serum did not show any definite precipitation after being kept for a short time at room temperature.

The complement fixation test was done in the following way: Decreasing amounts of antigen, volume 0.1 cc., were mixed with 0.1 cc. of diluted inactivated rabbit or human serum, respectively, and 0.1 cc. of a 1:20 diluted guinea-pig serum. The rabbit serums were diluted 1:10; the human serums, 1:5. The tubes were kept for one hour at 37 C., and then 0.2 cc. of sensitized sheep cells were added.

As can be seen from Table 1, rabbit serum No. 137 gave strong precipitation with an antigen dilution up to 1:1,600, while the patient serum gave only a weak precipitation in a dilution up to 1:100. In contradistinction to that, strong positive reactions were obtained with both rabbit and patient serum in high dilutions of the antigen with the complement fixation test.

The experiment given in Table 1 was one of the first ones carried out during the course of our investigations, and unboiled antigen

elimination of nonspecific reactions, however, constitutes an important advantage.

The first patient, A. K., whom we had the opportunity to examine, gave the following history: The patient ate roast pork on February 10, 1940. She stated that she might have eaten a piece of rare meat. On February 14, 1940, she felt weak and had frequent bowel movements. She suffered intermittent cramplike pains in the lower part of the abdomen but had no tenesmus. From then until February 17, 1940, these symptoms continued. On the fourth day after onset the abdominal cramps disappeared but diarrhea continued. Since the onset of the disease, the patient's face had become swollen. There was a marked conjunctivitis since February 23, 1940. The patient perspired profusely, especially at night. The white blood count was 27,750 with 48 per cent eosinophils. *T. larvae* were found in the blood sediment. An intradermal test with trichinella antigen obtained from the United States Public Health Service was positive. Muscle biopsy was done on February 27, 1940, and found to be positive for trichinosis.

The first blood specimen was obtained from

Conclusions

Serodiagnosis of trichinosis by complement fixation is described and its diagnostic application evaluated. The test is sensitive and specific. Boiled watery extracts of dried larvae are used as antigen. The test can be carried out as a quantitative procedure, and the increase and decrease of the antibody titer can be observed over a period of time.

. . .

We are indebted to Dr. W. H. Wright of the United States Public Health Service, Washington, D. C., for his most valuable suggestions and for material he placed at our disposal for our investigations.

Discussion

Dr. Ward J. MacNeal, *New York City*—This problem of trichinosis is now of considerable public interest. A committee of the State Legislature is engaged in its study with a view to enactment of law for protection against the parasite. I should like to ask Dr. Witebsky whether he has had opportunity to apply his diagnostic tests to the practical recognition of the disease in swine. Adequate blood specimens could doubtless be obtained from the tails of these animals

AMERICAN CONGRESS ON OBSTETRICS AND GYNECOLOGY TO MEET IN APRIL

The general features of the program for the coming Congress to be held in St. Louis, Missouri, April 6 to 10, are as follows:

The morning sessions will be divided into two periods, from nine-thirty to eleven, and from eleven to twelve. The more formal presentations will appear in the first period.

Monday morning at eleven o'clock there will be a general "Obstetric Information Please," based on the well-known quiz program and presided over by a moderator and four experts. This will be repeated on Wednesday morning for shock and hemorrhage and on Friday for economics. Clinical conferences on genital infections will be held Tuesday morning at eleven and Thursday morning on "How Not to Treat Carcinoma." During the afternoons various groups will present formal programs devoted to nursing, public health, and hospital administration, among which will be certain combined programs.

A special feature of this Congress will be a

daily consultation service at three-thirty. About fifty nationally known physicians will make themselves available for fifteen-minute consultations through a registration system by individual practitioners who may desire such advice in their specific problems.

Round-table discussions will also be arranged by the section chairmen.

Practical demonstrations are scheduled in the scientific exhibit area on manikin deliveries, home-care technic, and blood transfusions. Details of programs of other sections will appear shortly.

Further information is available at the Central Office of the Congress at 650 Rush Street, Chicago. Hotel reservations should be made directly and at an early date. Physicians, nurses, public health administrators, educators, and hospital administrators are urged to send in their registration fee of \$5.00.

—GEORGE W. KOSMAK, M.D.
Chairman, Professional Publicity

"WALK FOR VICTORY"

In a resolution recently adopted the Medical Society of the County of Erie pledged itself to encourage civilians to "walk around a block a day" so that the nation might become physically "toughened" for the war effort.

Dr. Harry C. Guess, in offering the resolution, cited the great use made by Germany of walking

tours to build up civilian health. The program, if found to be feasible, might one day become a national health project, he said.

"It will help the people mentally, too, by giving them at least twenty minutes for thought and reflection," he said. "We might use slogans like 'A block a day keeps the doctor away.'"

TABLE 4.—INFLUENCE OF INCUBATION TIME AND TEMPERATURE ON THE SENSITIVITY OF THE COMPLEMENT FIXATION TEST USING DECREASING AMOUNTS OF ANTIGEN AND A CONSTANT AMOUNT OF SERUM DILUTION

Dilution of Boiled Trichinella Antigen	Serum of Rabbit No. 150 Infested for Three Months	Normal Human Serum	Normal Rabbit Serum	Saline Control

cubator for one hour; and Part 3 was kept in the icebox overnight and then placed in the incubator for one hour at 37 C. To all tubes, 0.2 cc. of sensitized sheep cells were added. The first reading was taken after twenty-five minutes', and the second reading after ninety minutes', incubation at 37 C.

The experiment shows that there is a definite increase in sensitivity in Parts 2 and 3 as compared with Part 1. A surplus inhibition occurs in the higher serum concentrations with both rabbit and human trichinosis serums.

If the order of experiment is changed and serial dilutions of the antigen are mixed with a constant amount of serum, the same increase in sensitivity is observed as shown in experiment 4, which follows.

Decreasing amounts of antigen, volume 0.1 cc., were mixed with 0.1 cc. of (a) a 1:10 dilution of rabbit serum No. 150, (b) a 1:5 dilution of normal human serum, and (c) a 1:10 dilution of normal rabbit serum. One-tenth cubic centimeter of a 1:20 dilution of guinea-pig serum was then added to all tubes. Part 1 was incubated for one hour at 37 C. Part 2

was kept in the icebox for two hours and then transferred to the incubator for one hour at 37 C. Part 3 was kept overnight in the icebox and then placed in the incubator for one hour at 37 C. To all tubes, 0.2 cc. of sensitized sheep cells were added. The results given in Table 4 were obtained after the control tubes had completely cleared. The increase in sensitivity is evident from the preceding experiment and depends upon the length of incubation period to which the antigen-serum mixtures have been submitted.

Five more cases of trichinosis were examined serologically during the first few months of 1941. In 2 cases the diagnosis was confirmed by biopsy; in 3 cases no biopsy was performed, but clinical manifestations and history were suggestive of trichinosis. Two of the cases were of special interest inasmuch as negative tests were obtained before antibodies became demonstrable in the patient's serum. In 1 case (U.) it took six weeks for the test to become positive in a serum dilution of 1:5. The antibody titer of this patient rose to 1:640 ten weeks after infestation. The first positive serum specimen with a titer of 1:5 was examined with decreasing amounts of antigen and a constant amount of serum dilution (1:5). In this order of experiment the patient's serum reacted with an antigen dilution up to 1:8,000.

In order to see how the complement fixation test for trichinosis would work as an abbreviated routine procedure in serodiagnostic practice, two different methods were tried. The first method consisted of mixing several dilutions of boiled trichinella antigen with a constant serum dilution. The second method consisted of mixing decreasing amounts of serum dilution with a constant amount of trichinella antigen. Both methods seem to be feasible and might be recommended. In the first method a 1:500 and a 1:2,000 dilution of trichinella antigen were mixed with a 1:5 or 1:10 dilution of inactivated patient serum; it was kept for two to three hours in the icebox and then placed in the incubator for one hour. In the second method a 1:2,000 dilution of boiled trichinella antigen was mixed with serial dilutions of patient serum, such as 1:5, 1:10, and 1:20. The latter method is preferred by us. Out of 1,000 human serums examined in this way as controls, only one gave a definite positive reaction in both complement fixation and precipitation tests. This serum was obtained from a healthy blood donor who gave no history of trichinosis.

pared with the given standard color shades, thus establishing the required figures.

It is essential that the test be performed on many different locations on the skin of each individual whose acidity is examined. Not only the places that are affected by a dermatosis must be tested but also apparently normal parts, such as areas close to the affection and, possibly the areas localized symmetrically to the affection on the other half of the body. It will be seen that the figures are of value *only when compared with the pH found at the same time on the normal skin of the tested individual.*

Results on Normal Skins

Figures obtained by our method on the various skin regions of normals are as follows: face, trunk, upper and lower extremities, hands, and feet—pH 3.5–5.8; groins—pH 5.5–6.3; between the toes—pH 5.5–6.5; and in the armpit—pH 6.5–8.0. As a rule, values are more on the acid side on the forehead than on the cheeks and chin; more acid on the flexor surfaces of the arms and hands than on the extensor surfaces; more acid on the dorsal aspects of the feet than on the plantae.

It is noteworthy that the pH measured by our technic directly on the skin is often lower than the pH of sweat collected from the same place and immediately investigated. For example, on the skin (forehead) we found on a hot day a pH of 4.9; in the sweat collected from the same place, a pH of 5.4. This difference is easily explained by the fatty acids present in the skin which will not be drawn up into capillaries when collecting sweat. This shows why measurements have to be done *on* the skin proper when true values are to be obtained.

Salient and repeated deviations are the effect of certain external influences. As an example we note a difference of the values found on 16 persons during hot and during cool weather. There has been an increase in acidity when the temperature is high; the deviation varies individually in the order of two units of pH—for instance, from 5.8 to 4. This decrease of pH in hot weather cannot be explained merely by the increased excretion of sweat, for it has been stated that the acidity decreases during a continued excretion of sweat. To compensate for such a pH increase proportional evaporation is necessary, but to produce an increased acidity the evaporation must prevail. This appears to be the case on hot days. The tendency to a higher acidity in summer works out as a

physiologic process of protection because more germs approach during the hot days.

Another common outside influence able to change the pH on the skin is the use of soap. Our results concur with those of Hansen who found, normally, an increase of pH for about three and a half hours after washing with soap and water. This increase depends upon the quality of the soap used and upon the individual condition of the skin. Ordinary toilet soap and *sapo medicatus* do not usually cause a raise of the pH by more than 1–1.5, whereas *sapo kalinus* often effects an increase of 2.0. In the presence of some skin abnormalities where the pH is shifted toward the alkaline side, the influence of soap on the pH is both particularly marked and prolonged.

It follows from the foregoing that previous use of soap has to be considered when evaluating pH tests on the skin. The change of pH under the influence of soap suggests that the biologic buffer capacity on the skin is dependent upon the presence of the fatty acids, which are saponified and extracted by soap.

The effect of soap will surely cause frequent temporary variations of pH. Persons to be tested must be instructed not to wash themselves in the morning before examination.

In a discussion of the report on the influence of soaps on the hands of housewives by Jordan, Dolce, and Osborne, Parkhurst¹² suggested that the decrease of skin sensitivity to soap during summer might be explained by an increase of free perspiration. Parkhurst quoted Hansen who had found that the time of alkalization on the forearm after washing with soap was reduced to one and one-half hours when the person was perspiring freely. This is in agreement with our findings. The decrease of pH during the hot season explains the improved tolerance to soap in summer.

Results on Diseased Skin

Patients with various dermatoses have been examined by our method—namely, 16 cases of eczema, 8 cases of hyperhidrosis, 12 cases of dyshidrosis, 12 cases of superficial mycosis, 1 case of pityriasis rosea, 6 cases of psoriasis, 1 case of myxedema, 2 cases of senile atrophy, and 1 case of rosacea.

Generally, pH is higher on inflamed areas than on the normal skin of the same individual. This may be caused to a large extent by the lack of perspiration from the degenerated or “blocked” parts of the epithelium. However, by a closer analysis of our findings, additional factors able to modify the acidity on the skin came to light.

THE ACIDITY ON THE SURFACE OF THE SKIN

EUGENE TRAUGOTT BERNSTEIN, M.D., and FRANZ HERRMANN, M.D., New York City

SHARLIT and Scheer¹ demonstrated an acid reaction (pH 5.5) on the surface of the human skin. This observation has been confirmed and supplemented by a number of other authors^{2a,2b,6d} who have improved the methods.

The acidity depends chiefly on the quality of the sweat. Areas where free perspiration is possible were found to be more acid than locations where evaporation is slower. Thus, on forehead, breast, and "free" surface of the extremities, pH values of from 4.5-5.5 were reported, whereas pH values of from 6.0-7.0 were measured in the groins and between the toes. The mainly apocrine sweat in the armpit is still more alkaline (pH 6.1-8.1). Schade and Marchionini^{2a,2b} point out that the high acidity in the areas of free perspiration is due to concentration of fatty acids. Lowering of evaporation favors increase of alkalinity by decomposition of hydrated keratin.

The presence of certain acids (acetic, propionic, caproic, caprylic, lactic, and ascorbic acids) is a natural protection against parasitic invasions. An abnormally high pH means a breakdown of the physiologic "acid coat" of the integument; it provides a condition^{3a} favorable for the growing of several pathogenic germs—for example, of fungi. A number of dermatoses, particularly those caused by fungi, can indeed be cured by restoring the acidity of the skin—systematic stimulation of perspiration in a sweating box followed by a *thorough evaporation*.⁴

The electrometric method of pH determination gives the most exact figures and allows the measurement directly on the skin surface; thus, examination of circumscribed areas is possible, whereas other methods require a collection of sweat so that the area of investigation cannot be exactly limited. However, the potentiometric methods are rather delicate and the apparatus is rather expensive.^{2,3,6,7}

Several tests with pH indicator solutions have been used (first by Sharlit and Scheer,¹ then by Memmesheimer,⁹ Hansen,¹⁰ Scholtz,¹¹

and others). This procedure engenders the use of three different indicators. The test is, therefore, performed on a comparatively large area that may fail to possess a uniform acidity. Besides the technical inconvenience of using several indicator solutions, this method also lacks a satisfactory basis of comparing the color shade obtained, for the shade of the under-ground—namely, of the skin—varies in itself.

The so-called foil colorimeter also proved to be inaccurate for our purpose because of the membrane "error" and of the necessity of obtaining a sufficient sweat excretion. Furthermore, all kinds of absorbent papers, such as purified filter papers, were found to be deceptive when they were used to absorb the test fluid that was colored by an indicator. The shades obtained in the absorbent paper, compared with pH standard shades, indicate too acid figures.

A Simplified Method for Measuring Skin Acidity

This situation caused us to look for a simplified method of measuring skin acidity, which is as follows: The Stanscién universal indicator with a pH range between 1-11 has been selected. This indicator is dropped on the skin under *strictly comparable conditions*, is recovered in capillaries, and is compared with the given standard of colors. This procedure gives figures of sufficient accuracy. Thus, one of the two errors referred to by H. I. Blank has been overcome, the difficulty of evaluating the colors on the skin. The other difficulty, the possible interference of oxidizing or reducing substances, still remains, but this possibility has not proved to be of importance for our purpose because only wide differences have been considered to be significant.

The technic in detail is as follows: One drop of wide range indicator solution is dropped by pipet on the selected location. The size of the drop should be kept constant and should be stirred with equalized glass rods for five seconds each time. Immediately after this performance of the reaction, the test is drawn up into a capillary. The resulting color of fluid in the capillary* is com-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

From the Dermatologic Department of the Beth David Hospital. Service of Dr. Eugene T. Bernstein.

* A complete set with all utensils required for this test is obtainable at the Standard Scientific Supply Corp., New York City.

Case 2.—G. R., aged 19, is a slovenly youth with dirty skin. He has diffuse dermatitis on his hands and feet and in the groins. There is a strong fetor from the feet.

Noninfected Areas:

	pH		pH
Forehead	6.0	Hands	
Cheeks	5.8	Dorsal	5.9
Breast	5.8	Volar	5.9
Back	6.0	Feet	
Forearms	6.5	Dorsal	6.0
		Plantar	6.3
		Toes	6.9-7.1

Inflamed Areas:

	pH		pH
Distal Forearms	6.5	Groins	6.8
Fingertips	6.5	Toes	
		Dorsal	6.3

Case 3.—G. Ch., a boy aged 6, has a slight diffuse redness and inflammation on both feet, preponderantly in the spaces between the toes. He also has flat feet and fetor. His toes are closely pressed together, particularly the third and fourth ones.

	pH		pH
Forehead	4.0	Groin	5.0
Breast	5.0	Lower legs	
Axillae	6.0	Dorsal	4.0
Hands		Flexor	4.0
Dorsal	5.0	Feet	
Volar	5.5	Dorsal	4.0
		Plantar	6.0

Affected Areas:

	pH
Toes (between— on both feet)	
1st-2nd	7.0
2nd-3rd	6.5
3rd-4th	9.5

Areas Not Visibly Affected:

	pH
Toes (between 4th-5th)	9.0

Case 4.—A. K., a lawyer aged 41, habitually carries a heavy brief case. He has a circumscript parakeratotic dermatitis in the center of both volae manus, a slight erythema on the dorsum of both feet, a symmetric scaly inflammation between the third and fourth and fourth and fifth toes, and a localized dyshidrosis (plus epidermophytosis between some toes).

	pH		pH
Forehead	4.2	Feet	
Breast	5.8	Dorsal (ery- thema)	5.9
Forearms	4.8	Toes (epidermo- phytosis—be- tween)	
Hands (unaffected)		1st-2nd	7.0
Dorsal	5.9	2nd-3rd	6.5
Volar (close to affected area)	6.4	3rd-4th	7.6
Hands (affected—cen- ter of vola manus)	7.5	4th-5th	6.4
Axillae	7.0		

Evidently, dyshidrosis is characterized (and defined) by a marked lack of acidity.

One might raise the objection that the figures as well as the clinical aspect resemble eczema so much that a separation of the conditions is not justified. We must, however, consider that the increase in pH of dyshidrotic persons may be present persistently without

the interference of any dermatitis. A large part of the cases displays the characteristic disagreeable fetor due to the decomposition of sweat and the maceration of keratin, often associated with opaque hydration, desquamation, or reactive tylosis. If dermatitis is superimposed, it appears with the well-known blisters or with the characteristic red and soft plaques forming superficial lamellae, preponderantly localized on the volar aspects and in the intertriginous spaces of hands and feet. The pH is increased particularly in these spaces often giving frankly alkaline values, as a rule, considerably higher than in true eczema. Naturally, it remains a matter of subjective classification whether or not one assumes the dyshidrotic condition under eczema, too, but we consider a separation as indicated, because differentiation from eczema (and from the fungous diseases) is possible when considering the origin, the acidometric findings, and the clinical picture.

We enumerate once more the different possibilities that may cause dyshidrosis:

1. Low acidity of sweat from constitutional reasons—idiopathic or primary dyshidrosis (Case 1).

2. Secondary decomposition due to external influences. The most common causes of this shift toward the alkaline direction are dust or neglect of cleanliness (Case 2).

3. Decomposition with the consecutive lack of acidity due to insufficient evaporation: (a) from reason of anatomy, as between toes of certain individuals, in persons with flat feet, etc. (Case 3); (b) mechanically, by external covering or pressure, as when habitually carrying loads (Case 4), trusses, or prostheses.

Marchionini's conception of the nature of "bromidrosis" would make it come under (3a), but we disagree with his presumption that an increased perspiration, hyperhidrosis, is important for the development of this condition. It is obvious that the possibilities (2) and (3) occur more readily in persons with primary dyshidrosis (1) than in normals. But whether these changes appear in combination or single, whether they are associated with hypersecretion of sweat or not, they always represent one well-characterized condition that can be verified by pH determination.

According to Marchionini's experiments, the decomposing influence of some staphylococci—*Bacillus graveolens*, *Bacillus foetidus*, etc.—plays probably an important part for the increase in pH in dyshidrosis, particularly in conditions (2) and (3).

Dyshidrosis provides a disposition to fun-

Our findings in *eczema* agree with those reported before by Levin and Silvers.³ We note a moderate increase of pH on acute eruptions, a more marked one on subacute and chronic affections, and an outspoken one on the base of such fissures as often occur in chronic infiltrations. The inflammatory exudate plays a role in this reduction of acidity.

In our 16 *eczema* cases, which all have shown similar results, we found that the normal acidity is reduced not only on the affected areas but also on the seemingly unaffected surrounding, and even on far distant, parts. The deviation from the normal is lessened in sites distant from the affected areas. These results raised the question as to whether or not the increase in pH of the "normal" areas is a distant effect of the *eczema* or the consequence of an unavoidable lack of cleanliness or whether it precedes the affection for some reason, thus creating a disposition for the affection. All three possibilities have to be considered. The pH change is most marked in the advance stages of fresh eruptions even when the general status improves. The figures do not return to normal until some time after the disappearance of the visible manifestations of the disease. This observation is in accordance with the histochemical experience that a previously *eczematous* tissue may remain alkaline for a rather long time (three weeks) after the process has cleared up clinically (Gans¹³).

In 2 cases we had an opportunity to observe the skin pH of *eczema* patients under the influence of alkali—in 1 case, after a bath with sodium bicarbonate; in the other case, repeatedly after washing with water and *sapo medicatus*. The pH of the seemingly normal skin in the former case went up (to 8.5 on the lower legs) and did not return to the original values (6.5) until twenty-four hours after the bath. In the latter case the pH increased (to 7.2 on the dorsum of the hands) and did not return to "normal" (4.5) until ten hours after washing. These findings indicate a particular lack of fatty acids (see above) in *eczema*. We thus supplement Hansen's findings that in *eczema* positive patch test reactions with soap are rather "an expression for the reduction of the buffer value of the skin."

In *hyperhidrotic* conditions we find just what one would expect: The reaction, except the one in the axilla, is acid (3.2–5.5), somewhat, but does not excessively deviate from the normal average toward the acid side. On inflamed areas these figures are of the same order, thus suggesting that the

dermatosis is due to an excess of sweat. The abnormality is obviously not qualitative but is a quantitative one only. In 2 cases of retention of abundantly excreted sweat with a consecutive formation of vesicles (*miliaria crystallina*), the liquid contents have shown the same figures as the surrounding skin. The pH figures obtained in those vesicles are not excessively low, i.e., not lower than if there would have been no efflorescences at all. Our findings agree with those of Marchionini, who also had such an acid reaction in the vesicles of this type.

The classic condition due to *hyperhidrosis* is the formation of grouped vesicles as described by T. Fox¹⁴ (*dyshidrosis*). But *hyperhidrosis* does by no means lead regularly to inflammatory changes; nor are such changes, if they appear, bound to be vesicular and to be localized on the hands or feet. They may be micropapulous and may involve any area without demarcation. Thus, they may not differ from *eczema* except in the lack of the increase in pH.

The other one of the two most frequent conditions which may resemble a dermatosis merely due to *hyperhidrosis* is *dyshidrotic inflammation*. *Dyshidrosis* like *hyperhidrosis* is not necessarily conducive to inflammation. The fundamental difference between *hyperhidrosis* and *dyshidrosis* is to be seen in the merely quantitative nature of the former, and the qualitative abnormality present in the latter. *Dyshidrosis* can be associated with an increased excretion of sweat, but this is not the rule. These differentiations are justified by our results. All of the 12 cases of our group show remarkably high pH figures. These are found in some persons all over the body; in others, only locally, frequently on the feet, on the hands and feet, between the toes, etc. Four examples follow to illustrate the phenomenon.

Case Reports

Case 1.—G. H. A., a man aged 37, has no hypersecretion of sweat but does have *dyshidrosis* as indicated by the figures below. He has a tendency to acquire dermatitis, particularly on the hands and feet.

	pH		pH
Forehead	6.0	Feet	
Cheeks	6.1	Dorsal	5.5
Chin	5.9	Plantar	7.2
Breast	6.2	Toes	
Abdomen	6.5	1st–2nd	7.0
Axillae	8.0	2nd–3rd	7.2
Forearms	6.0	3rd–4th	7.2
Hands		4th–5th	7.5
Dorsal	6.3		
Volar	6.5		

Normal Areas:

	pH		pH
Forehead	5.0	Forearms	5.4
Face	5.0	Volar	
Breast	5.3		

Affected Areas:

	pH		pH
Skull	5.0	Breast	4.0
Face	5.0	Elbows	3.8

Case 8.—Y. B., a man aged 59, has had psoriasis for three months.

Normal Areas:

	pH		pH
Forehead	5.4	Thighs	6.1
Breast	5.3	Dorsal	
		Knees	5.0
Forearms		Dorsal	
Dorsal	5.3		
Hands			
Dorsal	5.1		

Affected Areas (Thick Scales):

	pH		pH
Breast	5.8	Thighs	6.4
Forearms		Dorsal	
Dorsal	6.3	Knees	6.2
Hands		Dorsal	
Dorsal	5.1		

Possibly the increased pH on the plaques of the second type is explained by the lack of a normally perspiring epithelium. The excessive para- and hyperkeratosis might have concealed the physiologic acid formation, as well as other changes in pH, in the deeper layers of psoriatic plaques.

Conditions with deficiency of eccrine sweat secretion have proved to be associated with a lack of skin acidity. Thus, the normally acidifying factor has been found missing in myxedema and in atrophic conditions, such as in senile atrophy. Accordingly, pH values have been found in the following 2 cases:

Case Reports

Case 9.—I. H., a woman aged 60, has had myxedema for one year.

	pH	pH (Nine and One-Half Hours After a Bath with Soap)
Forehead	6.2	6.5
Forearms		
Dorsal	6.3	6.9
Flexor	6.3	6.9
Hands		
Dorsal	6.3	6.9
Volar	6.3	7.0
Breast	6.3	6.5
Back	6.3	8.0
Abdomen	6.3	6.5
Axillae	6.5	7.0

Case 10.—G. H., a man aged 68, has had atrophica senilis.

	pH		pH
Forehead	5.8	Hands	6.1
Nose	6.2	Dorsal	
Cheeks	5.8	Volar	

In the case of myxedema, again the deficiency in fatty acids finds its expression in the fact that the figures have not returned to

normal nine and one-half hours after the use of soap.

Summary

I. (a) A convenient method of testing the acidity on the skin is described, using a universal indicator and capillaries.

(b) Additional evidence is given that the acidity on the normal skin is increased during hot days, that the skin is alkalinized by washing with soap, and that the reduced tendency to soap dermatitis in summer can be explained by the increase in (free) perspiration.

II. (a) In eczema the pH in the affected region is moderately higher than on the normal skin of the same individual. This change becomes manifest not only on the affected places themselves but also, to a less degree, on the normal surrounding region and on further distant areas. This change remains for some time after an apparent cure.

(b) Hyperhidrosis shows pH values that are either normal or on the acid side. These persist on hyperhidrotic, inflammatory areas.

(c) Dyshidrosis is characterized by a lack of acidity. This lack can be either (1) primary, idiopathic and generalized (most marked in intertriginous places, as in the spaces between the toes); or (2) secondary, caused by external factors, as uncleanness, dust, etc.; or (3) localized on places with reduced evaporation due to anatomic peculiarities; or (4) circumscribed, due to mechanical factors from outside.

(d) In intertriginous mycoses the figures are similar to those in eczema. A presence of fungi may be indicated by the finding of an "inner" area of lower pH within a surrounding zone of mere dyshidrosis which has a higher pH.

(e) The normal acidity is reduced when formation of compact scales, atrophy, or other degenerative alterations prevent the skin from imbibition with sweat; for example, myxedema and senile atrophy show low figures all over the body.

gous infection. Growth of fungi is favored by the lack of fungicidal acids (Peck, *et al.*^{8b}), as well as by a secondary increase of moisture, i.e., hydration of the keratin. It is, therefore, easily understood why ringworm infections are found with preference in intertriginous spaces, the axillae, the groins, between the toes, etc., and why dyshidrosis increases the susceptibility for these infections.

There is, however, restriction of fungous growth on the alkaline side, too. Marchionini found the pH on mycotic efflorescences near to the neutral point in contrast to both the alkaline figures in dyshidrotic dermatitis and to the acidity found in vesicles due to pure hypersecretion of sweat.

Although our own material does not yet allow definite conclusions, we can state that on the plaques of 10 cases of various primary mycoses (8 cases of epidermophytoses, 1 of which was associated with vesicular epidermophytid on hands and feet, and 2 cases of trichophytoses) pH was found to range between 6.3 and 7.5. These figures confirm Marchionini's⁵ and Levin's and Silvers' findings³ and to a certain extent (see below) Marchionini's suppositions. The figures show a deviation from those of the corresponding normal skin toward the alkaline. But their rather wide range causes difficulties in a differential diagnostic evaluation, and eczema, as well as dyshidrosis, can give similar figures. One peculiarity, however, characterizes the presence of fungi. It has been seen in 4 out of our 10 mycotic cases, all of which have been epidermophytoses, 1 localized on the hands and 3 in between the toes. Two examples follow.

Case Reports

Case 5.—Dr. H. S. T., a man aged 42, has dyshidrosis and epidermophytosis.

Normal Skin:

	pH
Hands and Finger	
Volar	7.3
Dorsal	7.0

Affection, Mainly in Interdigital Spaces: pH 6.3

Case 6.—J. I., a man aged 24, has dyshidrosis and epidermophytosis.

	pH		pH
Feet (unaffected areas)		Toes (affected areas—between)	
Dorsal	8.0	3rd—4th	6.5
Plantar	8.0	4th—5th	7.0
Toes (unaffected areas—between)			
1st—2nd	7.8		
2nd—3rd	8.5		

On the affected areas we see more acid figures than in the normal areas, i.e., noninflamed

surrounding regions. There is, therefore, a possibility of a differentiation if inflamed plaques show a lower pH, mostly near the neutral point, within a dyshidrotic area that has a high pH. According to the experiments of Peck, *et al.*^{8b} we may presume that this phenomenon is due to the ability of fungi to produce their own pH optimum.

An exception among the mycoses seems to exist in pityriasis versicolor, for in 2 cases we have obtained repeatedly acid figures not differing from the pH of the normal surrounding region (breast: in 1 case, 5.3; in the other case, 4.5). *Microsporon furfur* is obviously less susceptible to (the fungicide) acids than other fungi. Thus, the localization of pityriasis versicolor on the freely perspiring surfaces may be explained. In 1 case of pityriasis rosea we did not find any marked pH deviation on the lesions.

A review of the pH variations in conditions that may present equal or similar clinical features allows the following conclusions. The pH compared with the figures on the normal skin of the same individual is: (1) moderately increased in eczema, (2) unchanged or reduced in hyperhidrosis, (3) strongly increased in dyshidrosis, (4) moderately or remarkably increased in mycosis—a rate characteristic for fungous infection results only if the areas show a lower pH than dyshidrotic surroundings. It is evident that this differentiation will be of importance for diagnosis. In order to establish the practical value of the pH test in differential diagnosis, however, a more extended experience is needed. The particular value for insurance cases will be discussed elsewhere.

The few cases of psoriasis tested have shown divergent findings. In 4 patients the figures on the plaques have been the same or more acid than on the normal skin. These cases differ clinically from the other 2 by the lack of excessive desquamation, partly due to prior treatment, even though it had been discontinued some time before the performance of the test. An increased acidity is in agreement with the findings of Gans¹³ and others who proved, histochemically, a considerable acidity within psoriatic lesions. On the thick scales of the other 2 cases, the pH has surpassed that of the unaffected surrounding region. We give an example of each of these different states in psoriasis:

Case Reports

Case 7.—Y. P., a man aged 41, has had psoriasis for twenty-three years.

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the April 1 issue and will concern "Treatment of Pulmonary Tuberculosis from the Standpoint of the General Practitioner."

Treatment of Some Intestinal Infestations

DR. WILSON G. SMILLIE: The subject of the conference today is the treatment of the common parasitic infections of the intestinal tract. This will include not only treatment of the intestinal worms but also of amebic dysentery.

The discussion will be opened by Dr. Mackie, who will consider the clinical significance of the helminthic infestations.

Helminthic Infestations

DR. THOMAS T. MACKIE: I shall not attempt to discuss the use of the anthelmintic drugs but shall refer briefly to the indications for therapy presented by the various helminthic parasites.

The worm infections of man may be divided into two principal groups: the flatworms or cestodes and the roundworms or nematodes.

Of the flatworms there is only one that is really pathogenic for man—the pork-tapeworm, *Taenia solium*. Fortunately, it is rare in the United States. This parasite is dangerous to man because under certain circumstances man may become the intermediate host and harbor, in consequence, the larval form of the worm, the *Cysticercus cellulosae*. The adult tapeworm inhabiting the intestinal tract does not of itself produce disease. Under conditions of reverse peristalsis, mature proglottides or ova may be regurgitated into the stomach, and the action of the digestive juices liberate the contained embryos. These penetrate the mucosa of the stomach or the upper part of the small intestine, enter the blood stream, and are carried to various organs, particularly the brain, where they localize and undergo atypical development. The resulting cyst, the *C. cellulosae*, produces the pathologic picture of a slowly expanding tumor to which the clinical designation cysticercosis is given.

The normal intermediate host of the pork-tapeworm is the pig. Man becomes infected by the ingestion of undercooked pork. Fortunately, this parasite is rare, but the grave sequelae attendant on man's accidental function as an intermediate host render important the recognition and treatment of *T. solium* infestation.

The common tapeworm of man is the *Taenia saginata* or beef-tapeworm. The human cannot function as an intermediate host for this parasite and, consequently, harbors only the adult worm, which is acquired by ingestion of raw or too rare infected beef. Apart from symptoms resulting from the mechanical action in the intestine, particularly when more than one parasite is present, the *T. saginata* does not produce disease in the host. The indications for treatment, therefore, are not imperative.

The fish-tapeworm, *Diphyllobothrium latum*, has an interesting life cycle and medical history. In addition to man, the list of definitive hosts includes a number of fish-eating mammals. It is endemic in Northern Europe and is not uncommon in the northwestern part of the central United States. The ova excreted in the stool of the definitive host release the contained embryo in fresh water. They then parasitize a water insect, cyclops, within which they undergo partial development. Certain fresh water fish ingest the cyclops, the larval worms undergo further development in the musculature of the fish, and man becomes infected by eating the raw or poorly cooked meat of the fish. The adult worm then develops in the intestinal tract of man.

Historically, the fish-tapeworm is of some interest since, prior to the elaboration of the mechanism of pernicious anemia, infestation by this parasite was believed to be a cause of macrocytic anemia. This concept has been

Discussion

Dr. Herman Sharlit, *New York City*—This report carrying on the recorded interest of Hermann and coworkers in the "mass" character

of the chemistry on the skin surface is corroborative of most of the work already recorded in this field. However, the technic of the use of an universal indicator recoverable after application to the skin in capillary tubes for reading is ingenious and simple.

Unquestionably, the readings are most influenced by the imperceptible perspiration present at the site of testing, though definitely affected by sebaceous matter and protein detritus. There is yet to be established a meaningful application of studies such as these in clinical dermatology.

However, more and more correlations such as are presented in this report may eventually lead to clinically usable data. At any rate, the simplicity of their technic should serve to encourage others to similar interests.

WINTER DRIVING

The National Safety Council's Committee lists nine specific winter traffic problems and makes the following definite suggestions to traffic authorities and drivers on how to offset these added hazards of winter driving.

1. Reduced speeds and the use of tire chains when roads are slippery will help keep traffic delays and accidents at a minimum, particularly on secondary roads. Chains reduce the distance required to stop after brakes are applied on snow or ice by 40 to 50 per cent, as compared with bare tires.
2. Street and highway departments should improve secondary roads to facilitate snow plowing. Shoulders may need widening. Sharp turns, dips and other hazardous spots should be eliminated if possible.
3. New points of accident concentration or traffic congestion should receive effective snow and ice removal or treatment.

4. Drivers should check weather and road conditions before starting trips and postpone or interrupt trips when heavy snowstorms or fogs occur.
5. Reduce speeds at night. Use proper headlight beam—lower beam in snow storms and in fog, unless vehicle is equipped with fog lights.
6. A traffic safety educational appeal should be made to drivers in every community, warning them of the greater skill required for safe driving in winter.
7. Owners should have their vehicles inspected periodically for safe brakes, windshield wipers, lights, tires, etc. In snowstorms and fog, light beams aimed too high are reflected and blind the driver.
8. Commercial vehicle operators should allow more time for regular routes than during the summer.

PSYCHIATRISTS ORGANIZE TO TREAT WAR FEAR IN CHILDREN

A group of psychiatrists in New York City, with temporary headquarters at the Payne Whitney Clinic of New York Hospital, has formed a committee to prevent and treat mental disorders in children affected by air raids or other war upsets. The name—The New York Society for Child Psychiatry—has been tentatively adopted.

Dr. Lauretta Bender, senior psychiatrist at Bellevue Hospital, is the chairman. Another member of the organizing committee is Dr. J. Louise Despert, research associate in psychiatry at Cornell University Medical College, who explained the proposed work of the group.

At present there is no provision for specialized scientific handling of the problems of panic among children in case of air raids or sudden evacuation. The psychiatrists will offer their services to the Red Cross, the civilian defense authorities, city health and education departments and to other agencies that would be caring for children in emergencies. They will also offer instruction in how to prevent panic among children to air-raid wardens, nurses, teachers, and others. Another part of the organization's volunteer work would be with the emergency medical units. The program also calls for an increase in psychiatric research among children.

that hexylresorcinol is the drug of choice. Its great advantage is its safety. The chief limitation to its widespread use is its high cost. Oil of chenopodium, or its active principle ascaridol, is the most effective agent against ascaris, but the margin of safety is small. We have recently been reminded of this fact by newspaper reports of the death of a child given four times the usual therapeutic dose of chenopodium. Toxicity can be quite considerably reduced by administering chenopodium in castor oil. Carbon tetrachloride is probably the most effective agent for hookworm, but as we have said, it is a dangerous drug. Tetrachlorethylene, in adequate dosage, is probably as effective, or nearly as effective, as carbon tetrachloride against hookworm and is less toxic. The importance of iron administration in the treatment of hookworm was also discussed. The removal of the worms will not cure the anemia of hookworm unless large amounts of iron are made available. In the treatment of pinworm infestation, which has been considered one of the most difficult of the intestinal worms to eradicate, not only must a vermifuge be employed but also strict attention must be paid to general hygiene.

In what way should we now modify these statements of about three years ago?

In the first place, during the past few years progress has been made in the therapy of oxyuris or pinworm infestation. Heretofore, it has been found difficult to cure this infection by the usual methods of treatment which are based on a single dose of the anthelmintic. Frequently, repeated doses of the vermifuges available heretofore cannot be given with safety. The reasons for the failure of the single-dose treatment of pinworm infection have been clarified by the recent studies of Nolan and Reardon on the distribution of the ova of this parasite in household dust in homes where the family as a whole is infested. They demonstrated that this may be an air-borne infection. For instance, viable pinworm ova were recovered from nearly all dust samples obtained from every room in the house and from all levels—from top moldings of doorways and from ceiling lights—to which the ova could be transported only by air currents. Since living embryos were hatched from a considerable proportion of the ova recovered, it seems certain that pinworm infection can be acquired by inhalation of such dust. This might explain the persistence of pinworm infection in some adults who pay great attention to doctor's orders

and to personal cleanliness and in whom reinfection by the usually recognized means seems unlikely.

The likelihood of reinfection by inhalation of ova is an indication for a method of treatment extending over a long enough period of time to insure the death of all dust-borne ova. This apparently will take place during the course of a few days.

The repeated administration of gentian violet seems to satisfy these requirements. It has proved to be the most successful method of treatment of pinworm infestation yet devised. It was shown by Wright and Brady, and more recently by D'Antoni and Sawitz, that this method will cure about 90 per cent of these cases. Gentian violet is given orally in enteric-coated tablets. Several schemes of dosage have been employed—namely, 1 grain three times a day by mouth for eight days, followed by a seven-day rest period and then a similar course for eight days, making a total period of twenty-one days; or 1 grain three times daily for four five-day courses with a three-day rest period between each, making a total period of treatment of twenty-nine days; or $\frac{1}{2}$ grain three times a day continually for thirty-five days; or 1 grain three times daily for ten consecutive days. All of these courses have yielded about the same percentage of cures. A satisfactory plan is to administer $\frac{1}{2}$ grain three times a day for a couple of weeks, or a little longer if the patient will tolerate it, or to give 1 grain three times a day for a ten-day period provided toxic effects do not result. If toxic effects appear, the dose may be reduced or omitted for a day or two and then treatment resumed.

Gentian violet causes symptoms of gastrointestinal irritation. Quite frequently, it causes nausea, vomiting, or diarrhea. In most of the cases this does not seem to interfere much with the treatment, and serious toxic effects have not been noted. However, the drug has not been given to individuals with heavy ascaris infestation or with cardiac, renal, or hepatic disease, so we do not know how toxic it might be to such patients.

Since our last conference one of the significant advances in connection with anthelmintics is the clear-cut demonstration in animals that a specific acquired immunity to nematode infections may develop. Cort and Otto have recently reported that dogs subjected to repeated infections with small numbers of hookworms were not made ill by subsequent test inoculations with enormous numbers of

disproved, and it is now known that the effects of the fish-tapeworm upon man are limited to the mechanical effects in the intestinal tract. Various investigators have deliberately infected themselves with the *diphyllobothrium* and harbored the parasite for several years without untoward effects.

The second group, the roundworms, are more important from the standpoint of pathogenicity. Of these, the *Ascaris lumbricoides* is one of the commonest. Infestation is acquired by the ingestion of food or water contaminated by human excreta and containing mature ova. This parasite inhabits the small intestine and in the presence of heavy infestation, especially in children, may produce intestinal obstruction. The ascarides, likewise, may migrate into the common bile duct, the stomach, and even up the esophagus into the nose or paranasal sinuses. Probably all of you have seen the adults of this species. It is obvious from their size that their presence in considerable numbers may cause mechanical effects. This is their sole mode of action.

More important is the hookworm. It is unquestionably related to much physical and sociologic backwardness in many parts of the world and its effects have been notorious in certain parts of our southern states.

Under suitable conditions of soil and climate, the ova contained within human feces release an embryo which, after a period of free existence, develops the forms infective for man. These penetrate exposed skin and are carried by the blood stream to the lungs, whence they reach the small intestine via the trachea and esophagus. Here, they reach maturity, attach themselves to the intestinal mucosa, which they lacerate with cutting blades in the pharynx; and live literally at the expense of the host's blood. Heavy infestation by hookworm produces severe anemia due to chronic blood loss and causes a variety of gastrointestinal symptoms that are the reflection of mechanical irritation.

The *Trichinella spiralis* should likewise be mentioned because the incidence of the disease it causes in man, trichinosis, is increasing. Pathologic examinations of human diaphragms have shown that the general incidence is about 10 to 15 per cent of the sampling of the population. The pig is the important intermediate host, and man acquires the infection by eating underdone pork. It is important to understand that meat inspection cannot insure that meat is free from the larval infective forms. Infected meat,

however, is rendered safe for human consumption by refrigeration at low temperatures for a sufficient period of time and, likewise, by proper cooking. When infected pork is eaten, the larvae contained within the meat are released in the host's intestinal tract, burrow into the mucosa of the small intestine, and develop to maturity. Fertilization of the females occurs, and for a period of some two or three weeks the gravid females release living embryos which enter the blood stream and are transported throughout the body, localizing permanently in striated muscle.

The clinical picture that parallels these stages of invasion is a varied one. During the stage of invasion of the intestinal mucosa and the stage of propagation there is apt to be diarrhea and abdominal pain. During the period of migration through the blood stream there may be a severe skin reaction with scarlatiniform rash. This is not particularly common but is striking when present. The electrocardiogram may show transitory abnormalities. The larvae finally lodge in striated muscle where they become encysted. This last stage is accompanied by muscle pain and tenderness, which may be troublesome. However, no permanent disability results.

Pinworm infestation may be accompanied by pruritus ani due to irritation of the perianal skin which is produced by the migrating females that pass out of the anal canal for oviposition. In young children and infants heavy infections by this parasite may produce appendicular colic with many of the symptoms and signs of acute appendicitis.

DR. SMILLIE: Some pharmacologic aspects of the therapy of the helminths will be discussed by Dr. Travell.

DR. JANET TRAVELL: May I take a few minutes to review what was said at our conference on this subject about three years ago?¹

In considering the drugs used for the expulsion of intestinal worms, it was agreed that for tapeworms oleoresin of aspidium was the drug of choice. Hexylresorcinol and tetrachlorethylene are also useful but much less effective. Carbon tetrachloride is the most effective agent for flatworms, but its use in even the ordinary therapeutic dose is attended by the risk of serious poisoning and death. The likelihood of poisoning by carbon tetrachloride, however, can be greatly reduced by attention to certain precautions.

For the roundworms—except the whipworm and, of course, trichinella—it was agreed

¹ J.A.M.A. 113: 410 (July 29) 1939.

the efficiency of the anthelmintic by removing any worms that may have been only temporarily depressed by the vermifuge and which may subsequently recover, or to reduce the toxicity of the anthelmintic for the host. This last seems to be important. For instance, castor oil greatly reduces the toxicity of chenopodium. Similarly, castor oil reduces the toxicity of thymol, hexylresorcinol, and aspidium. This is supported by experimental evidence, although contrary statements appear in the literature.

Should the cathartic be given simultaneously with, or some hours after, the vermifuge? Usually, an interval of an hour or more is allowed to elapse between their administration, the theory being that the anthelmintic must be allowed time to act on the worms. Hall, however, has shown in dogs that chenopodium is as effective when castor oil or another purgative is given simultaneously or hours later and that santonin when given together with calomel is as effective as when it is followed hours later by the purgative. Since the main object of giving the purgative is to reduce toxicity, it would seem that this may be accomplished best by giving these two agents simultaneously.

DR. SMILLIE: In opening the discussion, I shall confine my remarks first to the questions Dr. Travell has raised.

Chenopodium is much less toxic if mixed with castor oil, but it is also less effective. We found this to be true in our dog and hog experiments, and in the worm count tests in humans we also found that mixing the two substances greatly lowered the effectiveness of the chenopodium. However, oil of chenopodium may be extremely toxic. If, for example, bile is added to oil of chenopodium and the two substances are given in capsules to a dog, death will result in a short space of time because the drug is absorbed so rapidly. Thus, the advantage to be gained by mixing castor oil with chenopodium is that rapid absorption of the drug is avoided, since the castor oil prevents rapid action on the chenopodium by the bile. This advantage applies especially to children. Severe intoxication with oil of chenopodium is most likely to occur in young children because they absorb the drug more rapidly than do adults.

Oil of chenopodium is a neurotoxic substance. The first symptoms of poisoning are tingling in the fingers and toes and then in the whole body. There is intense headache, projectile vomiting, prostration, and then convulsions. The convulsions are purposive

in type. In the dog they simulate running movements. Unconsciousness follows in five or six hours. Convulsions may be prolonged for twenty-four to forty-eight hours, and death will occur after many hours of agony.

The toxicity of carbon tetrachloride is due to the fact that it affects the liver directly. Small doses may produce a fatal termination. The average therapeutic dose of carbon tetrachloride is 3 cc. I have seen an individual die who received only 1 cc. of the drug. It is especially toxic in persons who have lately taken large amounts of alcohol. The cases of intoxication which we saw in the South and in Brazil were in individuals who had taken large amounts of alcohol just previous to the administration of the drug. The symptoms of poisoning appear in forty-eight hours or less and are accompanied by high fever and muscular pain and, shortly thereafter, by severe pain over the liver. The urine is suppressed and often contains large amounts of blood. The picture is that of acute central necrosis of the liver, which may be rapidly fatal.

Oxyuriasis is a family infection. If one finds infection in 1 individual, one should not treat that person only but examine all the members of the family. Most of them, if not all of them, will be infected.

You are familiar with Hall's newly devised method for the diagnosis of oxyuriasis. It consists simply of a small glass tube over which is folded a piece of cellophane the size of a cover glass. This is held in place with a rubber band. The whole is placed in a test tube. It is a small and convenient piece of equipment. The cellophane is rubbed carefully about the anal folds and picks up the ova to a surprisingly accurate degree. The test tube with its contents is then sent to the laboratory. It may be sent by mail, and a delay of several days is of no consequence. On reaching the laboratory, the rubber band that holds the cellophane in place is folded back, with a small pair of forceps the cellophane is placed on a glass slide, and when water is added it flattens out like a cover glass. A direct examination is then made with satisfactory results.

When treating families with oxyuriasis it is necessary to go into the general hygiene of the whole family in great detail. The children must be watched in relation to such things as short fingernails, and every attempt made to keep them from putting their unwashed fingers to their mouths because, of course, reinfection occurs largely from scratch-

larvae, up to 200,000, whereas practically all the litter mate controls not previously immunized were killed by the test infection. At autopsy, up to 30,000 worms were present in the intestine of the controls and only a few worms, 50 to 200, were contained in the intestine of the immunized animals that were sacrificed. This seems to be a conclusive demonstration.

The immunity to hookworm induced in the dog by repeated small infections is not absolute, since a few worms from the immunizing infections remain in the intestine and, if these are removed by chemotherapy, a few more worms develop when the animals are exposed to reinfection.

In the dog a number of factors may modify the phenomenon of immunity to hookworm. Age is one factor. Age resistance has been recognized for many years. A generally deficient diet—that is, a diet deficient in vitamins and proteins—or anemia may completely prevent the development of immunity. Moreover, a deficient diet may cause the loss of a previously acquired immunity. When the diet is made adequate again there is a rapid return of the immunity for the second or third time, as shown by the spontaneous loss of worms acquired while the animals were on the deficient diet. Thus, nutritional deficiency or anemia may seriously impair the mechanisms for the development and retention of immunity to hookworm infections.

The immunity of the host to nematode infections is general and not local. Cort and Otto have shown that dogs immunized by repeated oral inoculation with hookworm are refractory to test infections given subcutaneously and vice versa. Furthermore, the work of Taliaferro and Sarles indicates that the specific immunity acquired by rats to a nematode similar to the hookworm is largely dependent on humoral antibodies such as precipitins. These antibodies are formed chiefly in response to the secretions and excretions of the worms. Precipitates are formed around the worms in the tissues and in the intestinal tract of the host, immobilizing the worms and sometimes killing them. Otto has also shown that when the larvae of the canine hookworm are placed in the blood serum of immunized dogs precipitates appear around the mouths and excretory organs, whereas no such precipitates appear when the larvae are placed in the serum of nonimmunized dogs. Furthermore, larvae exposed to immune serum tend to lose their infectivity.

In human helminth infestations, the exist-

ence of specific immune substances in the blood remains to be demonstrated. However, we have no reason to believe that the host-parasite reactions in man differ fundamentally from those observed in the dog. If this is so, dietary deficiency and other debilitating factors, by interfering with the immune defense mechanism as in the case of the dog, would account for the occasional fatality or severe case of hookworm disease in a population that is pretty uniformly exposed to hookworm and harbors hookworms in the intestine almost continually. In this case measures to improve the nutritional status of the population may be more important in the control of nematode infections than is chemotherapy.

Next, I want to make some remarks on the subject of the use of cathartics in conjunction with vermifuges. There seems to be some confusion as to when and why cathartics are indicated, and I should like to raise certain questions for consideration.

First, has the purgative any anthelmintic action? Although an anthelmintic action has been claimed for castor oil, none has been demonstrated. Hall has shown that magnesium sulfate and castor oil are almost entirely ineffective as vermifuges.

Has the anthelmintic any effect on gastrointestinal motility? Oil of chenopodium has been reported as being constipating, and for that reason purgation may be indicated in the case of this vermifuge. On the other hand, this reason would not apply to certain other anthelmintics, such as carbon tetrachloride and areca nut, which themselves have a mild purgative action.

Why should a purgative be given prior to the vermifuge? Why is this procedure followed in the case of some vermifuges and not in the case of others? For instance, vigorous purgation is usually carried out preceding the administration of aspidium but is not recommended in the case of hexylresorcinol. That seems to be largely a matter of tradition. Theoretically, preliminary purgation should increase the anthelmintic effect by avoiding dilution of the drug by fecal material and insuring more complete contact with the worms. However, I do not know of any experimental evidence that shows that the use of a cathartic prior to a vermifuge increases its effectiveness.

The purpose of giving a cathartic after the vermifuge is said to be to avoid toxic reactions of the host to the so-called "endotoxins" of the dead worms in the intestine, to increase

DR. GOLD: Are we agreed that that is the most effective and least toxic?

DR. TRAVELL: Hexylresorcinol is certainly the safest and is quite effective.

DR. SMILLIE: It is not so effective as the other drugs, but the toxicity is so low it can be used to great advantage. A single administration removes about 80 per cent of the ascaris. *Chenopodium* removes 90 to 95 per cent.

VISITOR: I saw a statement by Faust that carbon tetrachloride is the most effective in the treatment of roundworms.

DR. SMILLIE: It is effective in roundworm treatment, but there are cases of severe intoxication by carbon tetrachloride.

DR. GOLD: I take it that we are not agreed on the answer to my question.

DR. MACKIE: I think the greatest difficulty with carbon tetrachloride is that there is so little difference between the toxic dose and the effective dose that it is quite possible to kill if great care is not used. This is true for *chenopodium* also.

DR. TRAVELL: The recent work of Best and his collaborators at Toronto gives promise of a means of protection against the disastrous toxic action of carbon tetrachloride on the liver. By the addition of large amounts of choline to the diet it has been found possible in rats to prevent almost completely the fatty degeneration of the liver commonly seen after this vermifuge. Calcium is also known to have an antidotal action in carbon tetrachloride poisoning, but the mechanism of protection by choline differs fundamentally from that afforded by calcium. Calcium antagonizes the symptoms of poisoning, thus permitting survival, but it does not prevent the pathologic process in the liver. Fortunately, if the poisoning is survived, the fatty degeneration of the hepatic lobules is apparently reversible. Choline, on the other hand, has a prophylactic value, at least in animal experiments.

STUDENT: Is tetrachlorethylene safer than carbon tetrachloride?

DR. TRAVELL: It seems to be. No deaths and no serious toxic effects on the liver after tetrachlorethylene have as yet been reported. However, Sandground recently described 2 cases of coma lasting several hours which followed shortly after the usual oral therapeutic dose of about 5 cc. of tetrachlorethylene. Two similar cases had previously been reported. All 4 patients recovered. This effect is in line with the well-known narcotic action of both tetrachlorethylene and carbon

tetrachloride, which is similar to that of chloroform. We probably have not yet had the full story of the toxicity of tetrachlorethylene.

Amebic Dysentery

DR. SMILLIE: We will take up next the treatment of amebiasis, which will be discussed by Dr. Mackie.

DR. MACKIE: I want to call your attention very forcibly to two misconceptions about amebiasis. The term amebic dysentery is ill advised, since dysentery is an uncommon manifestation of this infection. In the second place, the reference in the older literature to chronic treatment-fast infections is incorrect. The infection can be eliminated by proper choice and proper administration of the drugs that are available for therapy.

Perhaps it would be better before discussing details of treatment to state the problem. It is this: We are dealing with an infection of the colon, particularly the cecum. The amebae are present in the intestinal contents, on the surface of the mucosa, and likewise within the tissues of the mucosa and the submucosa. To effect protozoologic cure it is necessary simultaneously to destroy the amebae in each of these situations.

The antiamebic drugs fall into several different classes. The first comprises the pentavalent arsenicals—carbarsone, treparsol, and stovarsol or acetarsone. Treparsol and stovarsol are relatively efficient amebicides and have been highly recommended in the past. However, they are not an infrequent cause of arsenic poisoning. Carbarsone, on the other hand, most nearly approaches the ideal antiamebic drug. Its index of toxicity is low. It is active against the amebae in all these areas referred to, but it is not 100 per cent effective.

The hydroxyquinoline derivatives comprise the second group of which there are several preparations marketed under different trade names, including chiniofon, vioform, anayodin, and quinoxyl. These are not dissimilar chemically from the original German preparation, yatren. These compounds are effective against amebae in the intestinal contents and on the surface of the mucous membrane. Absorption is negligible and, consequently, they are ineffective against the amebae present in the tissues of the host. When used alone these preparations give only a low percentage of cures.

The third group includes the alkaloids of

ing around the itching portion of the rectum. It is necessary to pay particular attention to the sterilization of linen and underclothing, and the clothing that cannot be boiled or scalded should be ironed with a hot iron.

The prolonged treatment for oxyuriasis may seem to you to be entirely unnecessary. It is necessary because of the peculiar life cycle of this parasite. The fact that immature worms and mature males live in the upper part of the intestine and only mature females migrate to the lower part of the intestine makes it difficult to eliminate this parasite. Continuous treatment over a considerable period of time must be followed in order to be successful.

Dr. John Watt, a parasitologist working in my department, has recently done some interesting work on hookworm of rats, a parasite which is in many ways similar to the hookworm of dogs and human beings. He finds that immunity to rat hookworm infection may be transferred passively, and he has produced immunity in the younger rats by giving them serum from one of the older rats which has been hyperimmunized. In one stage of its life cycle the hookworm larva passes through the lungs, and in the immune rats the larvae are held there in a stage of retarded development; they may remain there for a considerable period of time. If an animal is put on a low nutritional basis, it may lose its immunity, and the larvae that were retarded now go on to complete development in the intestine of the rat.

Dr. Travell discussed the issue of nutrition versus chemotherapy in the control of hookworm disease. You will remember that Castle and Rhoads in their work in Puerto Rico suggested that all that one needed to do was to give plenty of iron to the patient with hookworm disease and, in many instances, the patient would regain normal health without the elimination of the worms by a vermifuge. Recent work has shown clearly that if one gives plenty of iron to these patients they do improve, even though one does not treat them at all for their hookworms. However, the relief is only temporary. It is obvious that one must first get rid of the parasite that is continually drawing blood from the patient. Nutritional treatment is supplementary, with the addition of iron, of course.

The disadvantage of the plan of administering the purgative with the vermifuge is that the former detracts from the full effectiveness of the vermifuge. This was shown in extensive experiments in South America; the purgative

was given at a measured interval before or after the vermifuge. The results showed that in hookworm disease a preliminary purgative is not necessary at all. It is quite necessary in the treatment of flatworms. The best time to give the purgative in the treatment of hookworm disease is one hour after the administration of the last dose of the vermifuge. This technic combines the least danger of toxicity with the greatest degree of effectiveness.

One roundworm was not mentioned which is of considerable interest because it causes creeping eruption. This infestation is quite common in the sandy coastal plain of the southern states. It is *Ancylostoma braziliense*, a hookworm of dogs. The normal life cycle of this worm is in the dog, but the larvae will penetrate the skin of human beings. When it does so, it does not seem to know what to do, so in its distress it simply burrows around under the skin instead of going through the usual life cycle. The worst case of creeping eruption that I ever saw occurred in a plumber who went under a house to do some plumbing work. The dogs were accustomed to defecate under the house and the larvae were there in the sandy soil. The plumber's entire back was a solid mass of creeping eruption. Treatment is relatively simple once the diagnosis is made. One freezes the skin in the area of the advancing worm. The difficulty is that one may freeze in one place because it seems that the worm is going to be there today, whereas the worm has really turned back or gone another way.

The subject is now open for discussion.

DR. HARRY GOLD: Is there any proof of immunity to any of these worms in humans?

DR. SMILLIE: No experiments have been done which have given proof of immunity. Is that right, Dr. Travell?

DR. TRAVELL: I do not know of any.

DR. SMILLIE: We think an analogy may be drawn from the results of the animal experiments.

DR. MACKIE: I think there is some demonstration of immunity by skin tests. Sensitization occurs, but there has been no quantitative estimation of the type that has been done in dogs.

DR. GOLD: Of the ten or eleven drugs that are used for treatment of roundworms, is there one that you would say is the safest and most effective, or are these two qualities not found in one and the same drug?

DR. MACKIE: It is hexylresorcinol.

and then without warning he may develop hepatitis or abscess of the liver. I have seen such an instance in an individual who apparently carried an unrecognized amebic infection for seventeen years without ever having dysentery. At the end of that period cholecystectomy was performed under mistaken diagnosis, and a few weeks later the condition was proved to be a large amebic abscess of the liver. Furthermore, there are numbers of less dramatic illustrations of deleterious effect upon the health of the infected individual. For these reasons, as well as for the possibility of infecting others, I feel strongly that every infected person should be treated. Furthermore, treatment is not hazardous provided the drugs are properly chosen and properly used.

DR. SMILLIE: These infections are not so rare as we think. In last year's class of medical students we had 1 case of ascaris, 1 case of hookworm infection, and several cases of oxyuriasis.

I am sorry that we must bring this interesting discussion to a close.

Summary

DR. TRAVELL: In this conference on parasitocidal agents, we considered the kinds of intestinal worms one commonly encounters, their life history, and their clinical significance. It was emphasized that the beef- and fish-tapeworms, apart from symptoms resulting from a mechanical action in the gastrointestinal tract, do not cause disease in man, whereas the pork-tapeworm is capable of doing great harm due to the formation of larval cysts in certain tissues. In the case of the roundworms, the migratory ascaris may produce serious symptoms by mechanical obstruction of the intestine, appendix, bile duct, and so forth. The chief effect of the hookworm is anemia resulting from the blood-sucking activities of the worm and chronic blood loss. Infestation by the *T. spiralis*, which like the pork-tapeworm is contracted by eating underdone infected pork, may be a serious disease

with varied symptomatology but, if recovery occurs, no permanent disability results. The pinworm causes symptoms due to local irritation around the anus or to invasion of the appendix. A hookworm of the dog may invade the skin in man, causing creeping eruption.

The methods of eradication of intestinal helminths were outlined briefly, as presented in detail at our previous therapy conference on this subject about three years ago. Hexylresorcinol is still the safest vermifuge. Tetrachlorethylene also appears to be safe, although its administration may rarely be attended by transient narcosis.

Among the important recent advances is the demonstration that the ova of the pinworm are dust-borne, a fact that helps explain why this parasite infests whole families and is particularly difficult to eradicate. Gentian violet is now being used advantageously for the treatment of pinworm, since it can be given in repeated doses over a long enough period to insure cure of all members of the family simultaneously and to permit the ova-laden dust to become sterile. A course of $\frac{1}{2}$ to 1 grain daily by mouth for ten to twenty days cures at least 90 per cent of the cases and produces only minor toxic symptoms, such as nausea, vomiting, and diarrhea.

In the treatment of amebiasis, it is important to remember that the organisms exist in two forms, cystic and motile. These are reached by different drugs because they are located in different places. Emetine attacks the amebae in the tissues; the hydroxyquinoline derivatives kill the free forms within the lumen of the gut, and carbarsone is active against the amebae in all locations. When either of these is used alone, a low percentage of cures is obtained. The disease is curable, however, at any stage, provided these drugs are properly used in combination and provided secondary bacterial infection does not present a serious problem. Emetine is, however, a dangerous drug, and its use should be attended by certain precautions.

COMPETITION

A high-powered orator we know was told off by one of the war charities to get a convention of undertakers to come across with a little something. Just before the meeting was called to order, the chairman took our friend aside and said, "Now, don't expect too much from the boys. Business has been very bad lately."

Our friend said politely that he was sorry to hear it, and added that he had always thought that particular business maintained a constant level. "Oh, no," the other man sighed. "Thousands of people who should be dead are walking around today—that sulfanilamide, you know."

—*The New Yorker*.

ippecac, the most important of which is emetine. There are several modifications of emetine for oral use, such as emetine bismuth iodide, all of which are irritating to the gastrointestinal tract and will not be considered here. Emetine hydrochloride for parenteral administration is the most important. It is a completely efficient amebicide for those amebae actually within the tissues of the host. It has no effect against amebae on the surface of the mucosa or within the intestinal contents. When used alone emetine will eliminate the infection from not more than 15 per cent of the cases.

The last group of drugs includes the compounds of bismuth. These are more of historic than actual therapeutic interest. Their index of amebicidal activity is low, and they do not properly belong among the modern antiamebic preparations.

Ambulatory cases may often be satisfactorily treated by carbarsone according to the following plan: A dose of 250 mg. is given twice daily for a period of ten days, and the course repeated once or twice with intervening rest periods of ten to fourteen days. However, infections may persist even after repeated courses of carbarsone and, if these fail, intensive treatment with emetine and one of the hydroxyquinoline derivatives should be employed, preferably under hospital conditions.

The acutely ill patient should be treated in a hospital or under competent nursing supervision at home. The patient receiving emetine should be in bed. It is a general protoplasmic poison, cumulative in action and slowly excreted. In overdosage it produces myocardial degeneration and cardiac death. For these reasons emetine should be given on the basis of body weight. The individual dose should not exceed 1 mg. per kilogram of body weight, and the total dosage in any one course should not exceed 10 mg. per kilogram. The course should not be repeated for at least two weeks. It is best given as the hydrochloride, one dose daily deeply intramuscularly. It should not be given intravenously. When given subcutaneously it gives rise to painful nodules at the site of injection which persist for considerable periods. Throughout the period of emetine administration, usually eight to ten days, one of the hydroxyquinoline derivatives such as anayodin should be given, 1 Gm. in enteric-coated pills three times daily before meals. These occasionally cause a moderately severe diarrhea which can, in almost all instances,

be controlled by complete bed rest and an appropriate dosage of paregoric. This combined or intensive method of treatment is completely effective.

DR. TRAVELL: I should like to ask Dr. Mackie if amebiasis is entirely curable by the combined method of treatment in all stages of the disease or only when treated in its early stages.

DR. MACKIE: At any stage it is curable if the drugs are used in the proper way and if the infection is not too much complicated by secondary bacterial invaders.

DR. TRAVELL: Which is more effective for eradication of the amebae within the lumen of the intestine, carbarsone or one of the hydroxyquinoline compounds?

DR. MACKIE: That is difficult to answer. Both will promptly make it impossible to find recognizable amebae in the stools of a patient with acute dysentery.

DR. TRAVELL: Owing to its high arsenic content, is carbarsone contraindicated in liver involvement such as amebic hepatitis or abscess?

DR. MACKIE: It is certainly inadvisable to use any of the arsenicals in the presence of liver disease, and it is not necessary to consider them under such conditions. Emetine hydrochloride is completely effective both in amebic hepatitis and amebic abscess of the liver. In the latter case it may be necessary to aspirate the contents of the abscess cavity.

DR. CHARLES H. WHEELER: One gets the impression that in the majority of the drugs used in the treatment of helminthic infestations, as well as of the amebic infections, the use of these drugs is attended with considerable risk. I wonder how worthwhile is it to treat some of these conditions when the treatment itself apparently carries such a risk, or does the risk exist only when the drug is used incautiously or improperly?

DR. MACKIE: The answer depends in part upon the clinical condition of the patient and in part upon the nature of the infection. For example, in the case of infestation by the tapeworm *T. saginata*, there is seldom a compelling indication for therapy. Likewise one not infrequently sees individuals with mild hookworm infestations. If they are normally residents of the North and if they have no anemia, treatment is unnecessary.

With amebiasis, however, it is a different matter. An infected individual may, over a period of many years, present little in the way of symptoms or signs that is noteworthy,

him already and I dread to think of the effect on him of the air-raid siren which is being installed not far from our home, and of worse noises which may follow.

Most babies are frightened by *sudden noise*—some more than others—but they can get used to a surprising amount of racket of many kinds and learn to ignore it. This takes time. Fortunately these young babies have no idea of the meaning of these military noises. Children in London have learned to draw the covers over their ears and many of them have slept through bombings quite peacefully. Unless they sense our own feelings of threat through our tense nerves and muscles, we can probably help the babies to accept the new kinds of racket in much the same way that we help them to live through thunderstorms or to sleep through the noise of elevated trains. Stay close to your child during unusual noises; let him feel your protecting body comfort. Playing a kind of game about it may help to relax both parent and child. Imitating an airplane or making other noises and translating into action the things of which he is scared may prove helpful.

If you happen to live where bomb shelters may have to be used, desert island games and special picnic parties held in the shelters from time to time may help to give these places an everyday feeling. This will make them less threatening to little children in case of real emergency. But don't be disturbed if some anxiety lingers on for a while. Your reassuring presence will do more than anything else to quiet him and eventually he is likely to get used to all kinds of noises.

Caution or Fear

How can parents avoid frightening their children and yet get them to take the necessary precautions for safety in case of air-raids? My children walk long distances to school every day and ought to know about signals and what to do. I am afraid that giving them information will only frighten them more.

It is not what or how much you tell your children that frightens them, but how you tell it. Let your manner be sensible and matter-of-fact. Of course you should give your children complete instructions, as these come from official sources. Then explain to them the reasons behind these instructions. Make what you have to say simple and brief. Don't go into a dozen or so remote possibilities. Don't repeat yourself, or beg your children to listen so as to be sure to understand what you are saying. They get you the first time. After you have told them, go about your business and let them go about theirs. Your composure and ability to attend to all the familiar routines will calm them more than any number of sermons on being calm. Fear in children comes not nearly so much from knowing the facts about possible dangers and how to meet them, as from a "hush hush" atmosphere, or from feeling that their own parents are jittery and that there is something that is being hidden from them.

Before They Understand

How much can my four-year-old understand

about the war? And how can I keep him from hearing all sorts of frightening things from his older brother and his brother's friends and even from some grown-ups? Every once in a while when he sees me looking troubled he says, "Haven't they caught Hitler yet?"

It is true that little children cannot understand what the war is about. They have no clear idea whether the fighting is near or far away or what it is like or what it all means. They are likely to catch only a mood of terror. Therefore "business as usual" and all the reassuring details and pleasures of their own small lives are the best thing for them. Young children will be better off if they don't hear constant war-talk. But neither should we try to avoid the subject altogether. Perhaps you can put it up to your seven-year-old that he, and his friends too, have a real "war job" right now in seeing that the younger ones don't get scared. That will mean watching their step with radio and conversations and seeing that others do too.

Yet we cannot completely protect even the young child from knowing that there is a war and that there is danger. In addition to thoughtless and idle talk there are likely also to be grim realities, and every family must take precautions. We can't pretend the war isn't here, and we will have to meet our children's questions whenever they come and at whatever age. The attitude which seems to say "don't bother your little head about such things" always defeats its purpose. Not only does this attitude give the child a feeling that he is not being told about something threatening, which makes it twice as frightening, but it also cuts him off from the comfort of being in on the whole thing with his parents. Even a small child who is puzzled and anxious may get a great relief from occasional direct and open talk about the war.

Just Being Together Helps

Isn't there a danger in our overdoing the stoical act at this time? Why pretend that nothing unusual is happening? When times are special aren't people's needs special too?

Of course you are right. Going about grimly pretending that life moves on in the same old way may not be the best thing for either parents or children. There is a kind of bravado which some people assume at this time which is emotionally unhealthy not only for themselves but also for the people who look to them for understanding and support. While going about our business quietly, let us remember, too, that we need both to find extra strength and to give it. Just being together is one enormous strengthener: let's not get so busy, even with war work, that we overlook the emotional needs of our own families. Most of us now feel the need for more evenings at home—we instinctively crave companionship with those who are closest. Even when we do and say commonplace things we get lots of comfort from just feeling that, come what may, we'll at least see it through together.

If you can't be with your family as much as you'd like, a thoughtful phone call now and then may help to bring that necessary sense that you're thinking of each other anyway. If you're going to be out of reach at times, have a standing ar-

Children in Wartime Parents' Questions

The following is reprinted from a pamphlet recently issued by the Child Study Association of America. The Child Study Association is a pioneer in the field of family guidance. Its staff conducts lecture-discussion groups in child development and parent-child relationships for parents, as well as leadership training and special courses for teachers, public health nurses and other professional workers. The Association maintains a Family Guidance and Consultation Service where, under the guidance of experienced counselors, parents and young people may come for advice and increased understanding of the problems they are called upon to meet. The Association also publishes a quarterly magazine, Child Study, and numerous books, booklists, and pamphlets. These services are available on a membership basis, or by special individual arrangement.*

The pamphlet reprinted below is the first of a series of "morale" on the home front" to be issued from the recently reorganized F Consultation Service, now under the direction of Dr. Bernard Glueck.—Editor

WHEN war strikes, parents' thoughts turn at once to their children. No matter how wide or unselfish our sympathies, it is perfectly natural that the first pang should be for the welfare of our own. If we have a son of fighting age there is little we can do but sit tight and give him our backing whatever happens. But if our children are younger there are measures to consider, not for their safety alone but also for their emotional well-being.

The attitude of parents as expressed daily in home life counts immediately and counts deeply. There are things we have already learned from England about children in wartime, and the most important is that so far as their morale is concerned, it is the parents who determine the mood. In the last analysis it is the tone in our millions of homes that will determine the tone of the nation. This means that parents in these perilous times feel a deep and special responsibility.

Whatever morale means, it means something more than a "front." It means more than grim silence or a pretense of courage. For families, it means a frank but balanced recognition of a common danger, and a feeling of confidence that, come what may, its members will stand by one another.

We have long known how foolish it is to try to deceive children. If a surgical operation has to be faced, telling a child that "it won't hurt a bit" is not the best way to help him through it. On the contrary, we tell him—briefly, to be sure—that it probably will hurt some, but that his mother will be right beside him. We know too that it is not our words that convince, but rather the child's feeling that his parents have matters under control, that they know just what has to be done and can do it. The same is true even of serious disaster. When death comes to a family and grief seems for a time to overwhelm and destroy everything, the child who finds that his parents do, after all, go on again with life and living, nearly always finds that he can, too.

If parents are to keep their own balance it is important that their demands on themselves

should not be superhuman. We are anxious—even fearful; and we are likely to be more so. There will be many times when we are tired and will feel and show the strain. We can't be models of absolute self-control, industry, and self-sacrifice. We can, however, comfort ourselves with the knowledge that such occasional breakdowns or signs of discouragement do no real damage. If the underlying loyalty is there the whole family will be sure to sense it and will find strength in it.

This was sharply brought out in the replies of many children evacuated from London during the period of severest air-raids, when questioned about their homesickness. What they most remembered was "my older brother teasing me," "my father growling about who took his newspaper." Evidently it is such familiar commonplace that spell home to us all and when we are most tried these are the things that stay with us.

British experiences show us, too, that among children the worst emotional upsets are likely to appear in the pre-school and in the teen ages. This bears out what we have always known—that even in normal times it is the very early and adolescent years that are the periods of childhood's greatest inner conflict. For children under seven the inability to grasp this large and threatening situation—to understand it or do anything about it—only increases the feeling of frustration and insecurity that go with being little. The recent rise in delinquency in Britain among children in the younger adolescent group also probably comes from frustrations. Young people always have a great need to do things, and when there is so much that needs to be done, ways should and must be found for making these older children feel that they are useful members of the larger group working to win the war.

Many questions will be asked by parents, not all of which can be answered now. New and unpredictable situations will arise. This booklet is issued in answer to some of the questions that parents have already asked of the Child Study Association and other agencies, in the hope of giving some help in the anxieties of parents and children in the present crisis.

Babies Need Not Be Frightened

My two-year-old is easily frightened by loud noises. How can I help him in these days? Sirens and low-flying planes have terrified

*Approximately 14,000 copies of this pamphlet have already been distributed, singly and in quantities. School superintendents have ordered them in lots of 500 to 2,000 to give to parents. Many other organizations and groups have assisted in their distribution.

Price: 5¢ per copy—3¢ per copy in lots of 100 or more. Child Study Association of America, 221 West 57th Street, New York City.

Learning to Obey

The air-raid warden in our apartment house has issued some directions which I question. And I am troubled, too, about some of the emergency regulations in force at my child's school. Must I see that my family obeys these rules when I really doubt their wisdom?

If each one of us attempts to make his own rules, serious confusion and danger to the whole community will inevitably result. In an emergency some official plan, by which everyone is guided, is of utmost importance. If you are not satisfied that the present rules are the best possible, it is your democratic privilege, as well as your obligation, to make suggestions for their improvement to the responsible authorities. But whether or not your suggestions are accepted, it is imperative that you obey and teach your children to obey. Conforming to the regulations is essential for the common safety. Having such regulations for our welfare made by our own representatives is of the essence of democracy. Our way of meeting the emergency is a test of democratic morale.

Most of us have lived in a world which made few demands on us for strict obedience and many of us have brought up our children under a system of discipline in which obedience played a minor role. It takes some readjusting for us to accept authority so unquestioningly now, and to help our children to do the same. This doesn't mean that our way was the wrong way. On the contrary, our kind of discipline is needed to create free people for a free society. But the present situation is a test of our *adaptability*. To no small degree our own readiness and willingness to make this adjustment will determine the ease with which our children do their part.

Mother's Work

How about the morale of mothers right now? If children depend so largely on mothers, what can be done to keep them from feeling useless and therefore discouraged?

The trouble with much of woman's work is that a great part of it—housework—is a lonely business. Now, of all times, we crave companionship with our own kind. Women have always found relief in keeping their hands busy with knitting and sewing and in the knowledge that this work brings comfort to the men who are fighting, or to children who need clothing. There is a particular satisfaction in doing this, or any other work for which they find themselves suited, *in groups*. Through the women's voluntary organizations, the local Red Cross and Civilian Defense offices most of us can find some group work into which our particular abilities—the things we can do best—will fit. New needs will be arising all the time, such as special help in the schools, in the church, through parents' associations, or in the local community.

It cannot be said too often that now is the time of all times when people of all ages need to herd together and to work not only for their fellow men but *with them*.

On Being Afraid

I am a somewhat nervous person even in normal times. Now everybody is telling us parents to keep calm. How can *anybody* be calm under these circumstances? I do my best to *appear* calm, but I am sure that my real feelings get through to my children. What can I do about it?

Don't try to be superhuman. Of course we are all more or less alarmed. Who wouldn't be? No use pretending that there just isn't a thing to worry about. But legitimate fear need not be allowed to become jitters. Let your children know that every normal person has certain dangers to face, and that it's natural to be on guard against them. Nobody really intends that parents should deny either the dangers or the fears. But emphasize the steps that are being taken to avert or to meet these dangers. Of course if you're going to turn pale and stop everything you're doing whenever an airplane passes overhead, you are going to communicate your state of mind to the children. But having acknowledged the realities, your children will be grateful to you for going on with your usual activities and keeping your home as normal as possible. There is something very reassuring and stabilizing in the carrying out of the usual routines.

Women and the Home Front

Is it the duty of every woman to find war or community work outside her home? Is she not serving her country just as faithfully if she attends to her own home, husband and children?

Certainly her own family in nearly every case is a mother's first responsibility. It seems a little foolish for women to rush around looking for war-work which may not yet exist and overlook their children's anxieties or other problems. The young mother with several small children can perhaps do no better than to give them all she has. Even in wartime there is no more important job than seeing that our homes are real havens of peace, warmth, and safety. Yet when we have done our best for our own, there are plenty of women who find that there is still time over, and who today feel as never before the urge to serve not only their own homes but the larger community too. Each woman will have to decide for herself whether she has energies to spare. There are times when a woman is a better mother for doing work outside as well as inside her home, and times when she is not.

Schooling or Service—Which?

What can we say to our children who cannot see the sense of going to school or college right now? Even the boys and girls of high school age are impatient about school and insist that they want to *do something* about the war.

Their feeling is natural. We all want to do something about it and wish we knew what. Yet very many of all ages can make their best contribution by going on with their regular work. Many young people should be encouraged to serve directly. Others of high school or even

rangement with your children as to how they may get in touch with a neighbor or family friend in case of emergency, or even if there is no emergency, when they just feel the need of homelike support.

Whistling to Keep up Your Courage

My boy of ten seems almost angrily indifferent to the war. He is impatient with our conversations and constant listening to news reports. Apparently all the instructions given him at school irritate him. He insists there is no danger and that people who think there is are just silly. How can I make him more aware of the seriousness of what is going on?

Don't be fooled. Whistling to keep up your courage is a well-known device. Maybe for this particular boy it is a necessary kind of refuge—each must find his own way. Probably behind all this belligerent indifference there is more anxiety than appears. Don't try to force a more realistic attitude upon him. He probably knows as well as you do what is going on. Maybe some day you'll find a chance to help him admit to more anxiety than he now shows. His discovery that it isn't "sissy" to admit his fears will be a healthy one.

Children manage their fears by different means, and react to danger in a variety of unpredictable ways. Don't be surprised at anything. The child who seems altogether indifferent may be the very one who will show his concealed anxiety in ways that are apparently unrelated. This is true of children, not only in wartime, but in any situation in which they can't admit their *real feelings*. Our experience with young children teaches us that they find ways of masking their feelings. For example, the unacknowledged jealousy of an older child toward a new baby may show itself in recurrences of bed-wetting, thumb sucking, disobedience, and other misbehavior even while he apparently "loves" the baby. Similarly the child with whom war-anxiety is largely unconscious and who shows only indifference may now take to bullying the younger child—to demanding extra attention from his parents, or to expressing his hidden fears, in many other indirect ways. Such misbehavior, while it lasts, will call for patience and understanding from both father and mother. In time, these children are likely to get their second wind and quiet down.

The Boy Who Is Thrilled with the War

My eleven-year-old son seems delighted at the war. His walls are full of maps; he gets the news eagerly. He and his friends talk constantly about going out and "blasting" Hitler. "Just my luck," he says, "to live where there is no fighting. Boy! Would I love to have an air-raid!" I find it hard to believe he is really so bloodthirsty. Is there anything I ought to do about it?

Remember that there is invariably a thrill at the thought of real danger. It would be less than human not to be excited and stimulated. In many children the love of adventure is very strong and quite natural and is not so "blood-thirsty" as it seems. The sight of the aggressive

primitive male animal, when he happens to be our own son, is likely to shock his mother, though rarely his father. But your son is not abnormal, and the kinds of feeling he is expressing are for very many—both younger and older—certainly natural right now.

Radio Listening—Is It Too Exciting?

What about the radio? Aren't we all overdoing it? Wouldn't it be better for the children *not* to listen so continuously? Along with the terribly exciting and often distressing war news, they are also getting the exciting dramatic programs. It all adds up to a pretty heavy diet of excitement. Yet the children seem to be drawn to it like moths to the flame.

Children are well aware of exciting things happening in the world around them, and radio offers one way for them to take part in these happenings vicariously. One of our greatest problems is to help children feel that they have a share in all this, that they play a part in it. The radio, addressing as it does each listener directly, makes the children part of the great world outside. There *are* limits, of course; and a steady, nonstop stream of continuous radio should be avoided. In fact, the children themselves often turn off the radio when they have had enough. Children and adults too can be appealed to for some moderation in this respect on a basis of common sense and household peace.

It is undesirable, moreover, for children to have too much excitement aroused with too little chance to drain it off in action. Adults must help to provide the antidote by seeing that the children have plenty of active things to do and that other interests are not crowded out entirely.

Playing at War

The boys on our block play nothing but war these days. Their belts fairly bristle with toy guns and makeshift war-planes are constantly zooming through the air. Isn't the world full enough of this sort of thing without the children having to play at it? How can we stop it?

Don't try to stop this kind of war play. Play is the language of children, their way of working out the matters that concern them deeply at the moment. Boys have always played games that gave release to their war-like feelings. Cops and robbers, Indian and cowboy, Lone Ranger, Superman, or war games have much the same root and much the same meaning for the players.

A certain amount of such play is needed by most normal young males at any time. Their need is even greater today when war surges all about them. Girls, too, feel this need now. They have to play out their heightened feelings, just as many of us older people need to talk ours out.

Up to a certain point this is perfectly healthy—a real safety-valve. You will probably find that the excitement dies down somewhat as time goes on. If not, some adult help may be needed to ward finding other, less exciting substitutes, especially athletic games, dramatics, and other more peaceful or "symbolic" expressions of rivalry and struggle.

Wyeth's **ELIXIR** **B-PLEX**

REG. U. S. PAT. OFF.

THE NATURAL **VITAMIN B-COMPLEX**

Current medical opinion states that most vitamin B deficiencies are multiple and therefore it is essential to treat such deficiencies with the complete vitamin B complex rather than with just the known synthesized B vitamins.

ELIXIR B-PLEX is a palatable elixir of yeast concentrate. It is a natural source of the water-soluble active constituents of a potent brewer's yeast containing the unidentified fractions as well as the known factors of B complex.

Write "ELIXIR B-PLEX, Wyeth" for your B avitaminosis cases.

Supplied in eight-ounce bottles.

JOHN & BROTHER, INC., PHILADELPHIA, PA
Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

college age will, for the present at least, serve their country best by continuing and in some cases intensifying their school work. Parents and teachers can rightfully point out to them how great the need will be for a generation trained and equipped to make a good peace and to rebuild a shattered world. School people have already begun to see that their work cannot go on as if nothing unusual were happening. Studies of many kinds will have to be re-directed so that school work will be more meaningful to youth in a world at war.

Yet we must expect these boys and girls to be restless and to demand some immediate part in the war effort. The best thought of our various youth organizations—Scouts, Y's, Boys' Clubs, Campfire Girls, etc.—should be given to finding ways of directing into useful community work the young people's energies and enthusiasms and capacity for high devotion. And parents and teachers should do their best to encourage the boys and girls to join in such projects.

For the young people in college—especially the boys of military age—the problem may be even more difficult. We can tell them how great will be the country's need for educated men in the days to come. But to many boys its present need for soldiers will seem more urgent. Combining study and military training in the R.O.T.C. will be a satisfactory compromise for many. To others immediate enlistment will seem the only course. Each must make his decision in accordance with his own conscience. For many the choice will be a difficult one. As parents we have not the right to interfere or to burden them further with doubts and reproaches. We have to recognize, too, that for many the opportunity to do war work is a welcome liberation from an otherwise meaningless or disagreeable program.

The Over-Anxious Child

In spite of all my efforts to "keep calm" (I am not a nervous person), my five-year-old daughter has been terrified ever since war was declared. Even before we went in she asked anxiously if every airplane she heard might not drop bombs. Now she has dreams and night terrors that her baby brother has been killed, that the enemy are coming right into the house. I have forbidden all war discussion, news broadcasts, etc., in her presence but it hasn't helped much. I am afraid that this will leave a permanent impression and upset her nerves for life. Is there anything I can do?

All the testimony of the British psychiatrists and others who have worked with children during the war shows that, like adults, children who are emotionally satisfied and generally well-balanced to begin with stand up well under enormous strain and recover even from what we might consider shattering experiences. Your saying that your child was afraid even before the war started raises the possibility that like many children from the age of two to six or seven, she has had some tendency to fears already. Her present state may be *intensified* by knowledge of real dangers, by hearing news bulletins and reports, but it is not *caused* by these things.

When children are continuously afraid of

bombs that *might* come, in terror for the safety of a father who is unlikely to be called, for a baby brother peacefully asleep in his crib, then we must realize that just as children fear giants or wild animals in peacetime, these are not the things which are really frightening them, but are only the symbols with which the real cause has been masked. The real causes are not in the outside world but lie within your child herself. Essentially she is afraid of certain of her own impulses and instincts which she has somehow learned to regard as "bad." She may be afraid, for example, because beneath the surface, she hates the baby, or is jealous of her father, or feels that some of her sex thoughts or acts are "forbidden." Bottling these things up tight within herself—so tight that she no longer knows they are there—she cannot shake off the feeling that punishment must surely follow; she sees it lurking all about her and uses "the war" or other current experiences merely to give it body or justification. Far too briefly and simply stated, this is the psychology of much of the exaggerated anxiety of those people who are forever dying a thousand deaths.

You may help your child by trying to improve all her relationships to members of the family and to outsiders, by raising her self-esteem in every way possible, and by allowing her angry feelings and her natural sex curiosity some expression. Children like these, if their parents will try to be especially reassuring and loving, usually grow out of this phase, and as their general morale improves their "war fears" tend to diminish. Meanwhile, such a child should not of course be subjected to constant reminders of danger, if we can prevent it. But it is important not to stop with such purely negative measures since the real causes lie elsewhere.

If, in spite of all you can do, the child's fears get worse instead of better, it might be well for you to get advice from professional sources.

Must We Teach Children to Hate?

Until recent events forced us into a horrible dilemma, my husband and I believed and taught our children that hate and war were the most destructive forces on earth. We taught them also to respect and believe in the reasonableness of human beings of all races and nationalities. Now there is an orgy of hate let loose. I believe my older children can keep their balance, but I dread the effect on the little ones. Must even the babies hate?

A few days before war broke out one of our radio news analysts said something like this: "I am going to say what within a week may be considered treasonous. I am going to say that in spite of all that has happened, Japanese are still human beings—Germans are still human beings. If Americans forget this, even though they win the war, they are in danger of losing the peace."

These are wise words, too wise perhaps for children to understand. But if parents believe them they cannot help making their attitude count with their children, even while they wholeheartedly give their full support to this war. Of course there are countless decent Germans and

[Continued on page 458]

These are the clear-cut advantages that have brought

NEO-SYNEPHRIN HYDROCHLORIDE

(laevo alpha hydroxy beta methyl amino-3 hydroxy ethylbenzene hydrochloride)

SOLUTION

EMULSION

JELLY

to prominence in the treatment of nasal congestion.

- Potent vasoconstriction—the ability to shrink engorged mucous membranes rapidly and efficiently.
- Prolonged effect—more prolonged than ephedrine.
- Low toxicity—lower than ephedrine in therapeutic dosage.
- No sting—relative freedom from unpleasant side-effects.

Recommended for relief of nasal congestion in colds, sinusitis, hay fever.

DOSAGE FORMS:

SOLUTION . ¼% for dropper or spray (1-oz. bottles)
1% for resistant cases (1-oz. bottles)

EMULSION . ¼% (1-oz. bottle with dropper)

JELLY . . . ½% (in collapsible tubes with applicator)

SYDNEY, AUSTRALIA

[Continued from page 456]

decent Japanese, and even many millions more who are just helpless and bewildered. But if we have brought up our children to believe that *all* people can be counted on to be just as reasonable, we have certainly deceived them and need to revise our teaching. Even the youngest child can be told that there are certainly dangerous people in the world, and when these get to be heads of government, they kill and rob people to get what they want. If their own citizens don't stop them, the time comes when others must do so. That means war.

Perhaps this is too detached a view for people who have lost and suffered through the evil doings of others; it is only one possible attitude. Each of us will have to find where he stands. Meanwhile, perhaps, the best thing we can do is to help our children to be fair to others of enemy alien descent with whom they come in contact and who are certainly not responsible for this war. If they really love justice they will not tolerate ostracizing the classmate whose parents come from Germany, or ridiculing Japanese children in their community, or stealing fruit from the corner grocer whose name and accent are Italian. Feeling as we do, we must oppose

these things even though in wartime they may be "natural." If we can keep a spirit of justice and kindness alive in this practical sense we probably need not fear permanent injury to our children's characters. If your children are emotionally sound, well-balanced personalities, all the wartime propaganda that they will run across in movies, radio, comics and elsewhere will probably leave them essentially unharmed.

Remember too that there is a real distinction between an unhealthy and destructive type of hatred and the righteous indignation that a normal person feels toward cruelty and injustice. There are some kinds of action that should *not* be tolerated and that we are glad to see our children hotly resent. It is well for them to hate the oppression of weaker nations by stronger ones, to hate the suppressors of freedom, to hate race and religious persecutions. When they see in such persons as Hitler and Mussolini the very embodiment of cruelty, they can hardly help hating them too—for these are today the flesh and blood symbols of all that is detestable in men, all that stands in the way of decent human living. There are some things worse than war, worse than bloodshed. These are slavery and degradation. Let us not be afraid to say so.

PHYSICIANS NEEDED IN THE PANAMA CANAL ZONE

Physicians are urgently needed at the Panama Canal—one of the nation's most vital defense areas. There is a splendid opportunity here for doctors to assist their country during the present emergency.

The U. S. Civil Service Commission has just announced an examination to secure physicians for these important positions. The entrance salary is \$4,000 a year, and free transportation by boat or plane is furnished from port of embarkation, the salary beginning on the date of departure from the United States. Applications will be accepted by the Commission in Washington, D. C., until further notice. There is no written test.

Applicants must have been graduated from a Class A medical school with a degree of M.D. subsequent to May 1, 1920, and, in addition, must have had at least one year of experience in a hospital since graduation. Graduates from schools that require the completion of the internship before granting the M.D. degree (five-year schools) will be regarded as having met the hospital experience requirement. Applicants

must not have passed their fiftieth birthday; however, because of the arduous duties in the tropical climate, applicants between 25 and 35 years of age are preferred.

Applicants must be in sound physical health; they must be active and capable of arduous work. Although appointees are required to pass a thorough medical examination, the physical requirements are not so high as for the Army or Navy service.

The duties of the position are to serve as district physician in a small government dispensary; have general supervision over all medical and surgical activities in the dispensary; operate a general medical and surgical clinic; examine persons entering the Panama Canal Service; visit patients day or night in their homes and on board ship; and be in charge of business activities of the dispensary.

Further information is given in the announcements that may be obtained, with application forms, at any first- or second-class post office, or from the U. S. Civil Service Commission, Washington, D. C.

JENNY OR JOHNNY? BUT HAVE THEM READY

Thirty thousand birth certificates, or one out of every four of the new birth certificates received last year by the Health Department, lacked the first name of the baby or the middle name, declared Health Commissioner John L. Rice in a recent radio address. He stated that this was due to the fact that the parents didn't make up their minds what to call the baby before the attendant physician sent in the required birth certificate.

"The 30,000 birth certificates that came in last year without the baby's given name," said Dr. Rice, "involved extra clerical and stenographic work for the Health Department. This extra time is needed right now to help out with the certificates for the men and women who want to get into defense work. The fewer birth certificates we have to correct or change, the more certificates we can get out for the adults every day."

SHOCK ABSORBER

Theelin acts as a therapeutic cushion to help absorb the physical and mental shocks so often caused by ovarian hypofunction during the menopause. Theelin accomplishes this by replacing or supplementing declining ovarian secretion until such time as the endocrine system can adjust itself to the hormonal deficiency. Its clinical reputation is firmly established on the basis of millions of doses successfully used. Indications: the climacteric, senile vaginitis, kraurosis vulvae, gonorrheal vaginitis in children, and certain other conditions due to estrogenic insufficiency. Theelin was the first estrogen to be isolated in pure crystalline form. Each lot is physiologically and chemically standardized before release by the laboratories of Parke, Davis & Company and by the Biochemical Laboratory of St. Louis University. Theelin Suppositories for vaginal use and Kapseals Theelol for oral administration are available where sustained therapy between injections is desired.

Maternal Welfare

From time to time under this heading articles appear on obstetric subjects which are deemed of importance as aids to improvement of maternal welfare in New York State. The members of the Committee are Charles A. Gordon, M.D., chairman; Alexander T. Martin, M.D.; James K. Quigley, M.D.; and Ferdinand J. Schoeneck, M.D.

Standards for the Care of Pregnancy Complicated by Heart Disease, Part II

THE following article is the second and concluding portion of the Standards as published by the Maternal Welfare Committee of the County of Kings. The first half of the article appeared in the February 15 issue.

Shall the Cardiac Patient Be Advised to Avoid Pregnancy?

Just because a woman has organic heart disease, it is not necessary to advise her to avoid pregnancy or to interrupt an existing pregnancy.

Many women with organic disease of the heart are able to have babies apparently with little or no ill effect, provided the size of the family is not too large. Women with organic disease of the heart will not tolerate, as a rule, more than three pregnancies.

It is the woman with serious disease of the heart who should be advised against becoming pregnant.

What do we mean by serious organic disease of the heart?

First, those who have had an attack of cardiac decompensation should not become pregnant. Once a heart has failed under the ordinary strain and stress of life, that heart usually will not withstand the strain of pregnancy.

Second, women who functionally are in Class 3—that is, those who are not able to carry on the stress and strain of ordinary life without great discomfort—are not good subjects for pregnancy.

Third, gestation in women in Class 4 is dangerous, and such women should be urged not to become pregnant.

Fourth, the anatomic type of cardiac lesion must be considered. Women whose hearts are definitely enlarged withstand pregnancy badly—the larger the heart, the greater is the likelihood of the occurrence of decompensation.

The finding of a long rumbling diastolic murmur at the apex in mitral stenosis is not a favorable sign. This usually denotes a high degree of stenosis of the mitral valve.

Women who have had rheumatic disease of the heart for over fifteen years are usually not good risks, nor are those over 35 years of age.

Young women who develop an attack of acute rheumatic fever or chorea should be advised to avoid pregnancy for at least two years after the subsidence of the attack. An acute attack of chorea or rheumatic fever occurring in a cardiac patient during pregnancy is rare and serious. Interruption of the pregnancy may become necessary.

In the older age group, women with auricular fibrillation should never become pregnant. They usually decompensate in pregnancy.

Care of the Patient During the Prenatal Period

In addition to the usual prenatal care, cardiac patients should be carefully evaluated early in pregnancy by a competent cardiologist who is familiar with the stress and strain of pregnancy and labor. Consultation and supervision by the cardiologist should be continued throughout the pregnancy.

A diagnosis should be made of the anatomic lesion, and the patient should be grouped according to the classification of the New York Heart Association as approved by the American Heart Association.

The obstetrician and cardiologist should consider:

1. Whether the patient can probably be carried to term; the type of delivery to be chosen as it seems best when term is reached.

2. Whether she can probably be carried to viability and be delivered by cesarean, with or without sterilization.

3. Whether her condition is serious enough to warrant immediate interruption of the pregnancy, with or without sterilization.

There is no specific preventive treatment for cardiac disease. Prevention of decompensation is the goal for which we strive in the care of these patients.

For prevention of decompensation the important factors are:

1. Frequent observation and examination for early signs of decompensation.

2. Avoidance of physical efforts that might cause extra strain on the heart.

3. Employment of visiting housekeepers in the home.

4. Avoidance of excessive gain in weight.

5. Prompt digitalization for early signs of congestive cardiac failure.

6. Absolute bed rest in a hospital if decompensation occurs.

If the patient decompensates during pregnancy, she should be vigorously treated. Under no circumstances should the pregnancy be terminated until compensation has been restored or until the patient has recovered as much as is probable. Then, the pregnancy may be terminated. If decompensation continues, operative

ARGYROL

SAFE

EVEN IN THE CAVITIES

Effective Antisepsis without Toxicity: Decongestion without Vasoconstriction.

The fact that ARGYROL has been employed repeatedly in the sinuses, the renal pelvis, and the bladder with good effect, and always without undesirable toxic effects, is evidence of its complete freedom from systemic toxicity. But ARGYROL also has many other advantages which make it truly "the mucous membrane antiseptic of choice."

No Ciliary Injury. The "ciliary sweep" is a vital factor in throwing off upper respiratory infections. ARGYROL, despite its protective consistency, does not injure ciliary action.

Decongestion Without Vasoconstriction. It is a common observation that the continued use of vasoconstrictors may lead to soggy

and loss of tissue resiliency. ARGYROL lessens turgescence but induces no powerful artificial vasoconstriction.

Unique Physical Properties. ARGYROL is more than just a chemical germ-killer. Its mechanical action is detergent and pus-dislodging. It is demulcent, soothing and inflammation-dispelling. It effects a "physiological washing of the mucous surface."

ARGYROL'S colloidal dispersion is finer, and the hydrogen ion concentration and silver ion concentration of ARGYROL solutions are carefully and properly regulated, so that solutions of ARGYROL in any strength from 1% to 50% are equally bland and non-irritating.

A. C. BARNES COMPANY, NEW BRUNSWICK, N. J.

delivery will be of little avail, and it will be wise to let nature take its course.

Care of the Patient During Labor

The labor and delivery should be in a hospital. Cardiac disease is too serious a complication of labor to allow the patient to be delivered at home. It is good policy to hospitalize the patient for observation at least two weeks before the onset of labor.

Delivery by cesarean section is only occasionally indicated. The patient may be ill as a result of the operation, and her convalescence may be complicated. Delivery by cesarean section should be advised in cases when known dystocia is present, when dystocia develops early in labor or when, at the onset of labor, the patient shows symptoms of impending decompensation. In the primipara, and especially in the elderly primipara, cesarean section should be preferred to a long labor. If she should decompensate during pregnancy, a cesarean should be done when compensation has been restored. The anesthetic of choice is local or open drop ether with oxygen.

In general, if the patient has no signs or symptoms of decompensation at the onset of labor and if there is no observed or probable dystocia, delivery will be best accomplished by allowing the patient to go through the first stage of labor under considerable morphine analgesia, with forceps delivery under local anesthesia, or open drop ether-oxygen anesthesia, as soon as the cervix is fully dilated. The cardiac requires a maximum amount of rest and analgesia during labor.

The expulsive efforts of the second stage of labor are harmful to the cardiac patient. Therefore, she should usually be delivered as soon as the cervix is fully dilated.

Care of the Patient During Puerperium

Mental and physical rest are extremely important during the puerperium.

If the patient is decompensated after delivery, proper treatment for that condition should be instituted. She should be kept in bed for a minimum of two weeks and examined by a cardiologist before she is allowed out of bed. She should then, if her condition warrants, be allowed up for only short intervals each day for a period of a week. She must take on her usual duties slowly and avoid exertion, particularly during the first few months after she is ambulatory. Each pregnancy shortens the life expectancy of the cardiac patient.

Except in mild cardiac patients, nursing the baby is to be avoided. The breasts should be dried up as soon as lactation begins and the baby bottle fed.

Visiting nurses and visiting housekeepers will be of great benefit to the cardiac mother after she returns home from the hospital.

Follow-up Care of the Patient

Every cardiac patient should be under regular observation at monthly intervals, or oftener if she requires it, for the first six months after pregnancy. Thereafter, the follow-up may be at more infrequent intervals, but she should never be discharged from medical observation.

She should now be carefully evaluated and advised with regard to the avoidance of future pregnancies or sterilization.

Patients with cardiac murmurs should be thoroughly evaluated early in their pregnancy. If the patient shows evidence of definite cardiac disease, it will be wise to consult with a cardiologist for definite diagnosis and suggestions as to treatment.

The obstetrician should confer frequently with the cardiologist, and the latter should see and examine the patient periodically during pregnancy, labor, and the puerperium. It is only by this dual observation and treatment of pregnancy complicated by cardiac disease that the patient can be carried through her pregnancy, labor, and puerperium in the most careful and successful manner.

AWARD TO BE GIVEN

The American Urological Association offers an annual award, not to exceed \$500, for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the award is based on the merits of the work presented and, if the Committee on Scientific Research considers none of the offerings worthy, no award will be made. Only residents in urology in recognized hospitals and physicians who have practiced urology for not more than five years may compete.

Essays should be in the hands of the secretary, Dr. Clyde L. Deming, 789 Howard Avenue, New Haven, Connecticut, on or before April 1, 1942.

SECTION ON ANESTHESIOLOGY

The program committee of the Section of Anesthesiology wishes to announce that questions desired brought up for the Round Table discussion to be held at the State meeting April 29, 1942, at the Hotel Waldorf-Astoria be mailed to the secretary of the section: Dr. M. C. Peterson, 303 East 20th Street, New York City.

The topics for discussion are: (1) Inhalation Anesthesia, (2) Regional and Spinal Anesthesia, (3) Inhalation Therapy, and (4) Resuscitation. The members of the Round Table Panel are: Dr. F. A. D. Alexander, Dr. E. J. Delmonico, Dr. M. C. Peterson, Dr. E. A. Rovenstine, and Dr. Paul M. Wood.

Chemotherapy

OF THE PNEUMONIAS

Sulfathiazole exerts a pronounced and rapid bacteriostatic effect upon the most common causative organisms of pneumonia (pneumococci, hemolytic streptococci, staphylococci). It is not necessary to delay treatment of pneumonia until the laboratory report on sputum typing has been received.

In the vast majority of cases Sulfathiazole is administered by mouth; occasionally it is necessary to resort to injection. Only in certain circumstances is specific serum also indicated.

Write for booklet on Sulfathiazole which includes also a discussion on the treatment of gonococcus and staphylococcus infections.

HOW SUPPLIED

Tablets of 0.5 Gm. (7.72 grains), bottles of 50, 100 and 500.
Also primarily for children tablets of 0.25 Gm. (3.86 grains), bottles of 50, 100 and 500

Powder in bottles of 5 Gm., $\frac{1}{4}$ lb. and 1 lb.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York will henceforth be published in this section of the JOURNAL. Members of the committee are Oliver W. H. Mitchell, M.D., chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

Joint Program

A joint program has been arranged for *Delaware and Otsego County Medical societies*. The lectures will be held on Friday evenings, at 6:30 P.M., with dinner at the Oneonta Hotel, Oneonta, New York.

March 13.—Relation of the Family Physician to the Cancer Problem.

Frederick S. Wetherell, M.D., associate professor of clinical surgery, Syracuse University College of Medicine, Syracuse.

March 27.—Bursitis, Sprains, Strains.

Willis W. Lasher, M.D., assistant clinical professor of surgery, College of Physicians and Surgeons, Columbia University, New York City.

April 10.—The Treatment of Burns and Hand Infections.

David Goldblatt, M.D., assistant traumatic surgeon, Post-Graduate Medical School, Columbia University.

April 24.—Fractures in General. The Treatment of Common Fractures.

Henry H. Ritter, M.D., professor of clinical surgery, New York Post-Graduate Medical School, Columbia University.

May 8.—Prenatal and Postnatal Care; Care of Newborn; Pelvimetry.

Merton C. Hatch, M.D., instructor in obstetrics, Syracuse University College of Medicine.

May 15.—Toxemias of Pregnancy.

Edward C. Hughes, M.D., professor of clinical obstetrics, Syracuse University College of Medicine.

May 22.—Rheumatic Fever—Rheumatic Heart Disease.

Alexander T. Martin, M.D., clinical professor of pediatrics, New York University College of Medicine, New York City.

The lectures on cancer, obstetrics, and rheumatic fever are given in cooperation with the State Department of Health and the Medical Society of the State of New York.

Traumatic Surgery

A course in traumatic surgery was arranged by Dr. Henry H. Ritter, Reconstruction Unit, New York Post-Graduate Medical School, Columbia University, New York City, for the *Cayuga County Medical Society*. The meeting on March 3 will be held at 4:00 P.M. in the staff rooms of the Auburn City Hospital, Auburn, New York.

The remainder of meetings will be held at 8:30 P.M. in the same place.

March 3.—Surgery of Trauma; Treatment of Burns.

Henry H. Ritter, M.D., professor of clinical surgery, New York Post-Graduate Medical School, Columbia University, New York City.

March 10.—Fractures of Leg and Ankle.

Walter D. Ludlum, Jr., M.D., New York City.

March 17.—Head Injuries.

Carl A. Peterson, M.D., New York City.

March 24.—Hand Infections.

Ernest W. Lampe, M.D., New York City.

March 31.—Fractures of Forearm, Wrist and Hand.

Willis W. Lasher, M.D., assistant clinical professor of surgery, College of Physicians and Surgeons, Columbia University.

April 7.—Fractures of the Femur.

Emmett A. Dooley, M.D., New York City.

April 14.—Treatment of Wounds, Tendons, and Nerves.

David Goldblatt, M.D., assistant traumatic surgeon, Post-Graduate Medical School, Columbia University.

War Medicine and Surgery

Fracture Lecture

A single lecture, arranged for *Onondaga County Medical Society*, is to be held at Syracuse University College of Medicine, Syracuse, New York, on Tuesday, March 3, 1942, at 8:30 P.M.

Fractures in General. Treatment of Common Fractures.

Henry H. Ritter, M.D., professor of clinical surgery, New York Post-Graduate Medical School, Columbia University, New York City.

Neurology Lecture

A single lecture, arranged for *Monroe County Medical Society*, is to be held in the Academy of Medicine Auditorium, Rochester, New York, Tuesday evening, March 17, 1942.

Nervous Conditions Associated with Warfare. Foster Kennedy, M.D., professor of clinical neurology, Cornell University College of Medicine, New York City.

A pat on the back develops character. . . . if administered young enough, often enough, and low enough.

County News

Broome County

Dr. Silas D. Molyneaux, chairman of the Preparedness Committee of the county society, reported on "A Unified Plan for Emergency Treatment in Major Disaster" at the February meeting of the society.

Other physicians who took part in the program and their subjects were: Dr. Charles D. Squires, "Emergency Treatment of Open Wounds"; Dr. H. J. King, "Emergency Treatment of Burns"; Dr. C. L. Pope, "Emergency Treatment of Fractures Referable to Spine and Extremities"; Dr. C. B. Henry, "Emergency Treatment of Compound Fractures"; Dr. M. H. Williams, "Emergency Treatment of Chest Injuries"; Dr. J. Worden Kane, "Emergency Treatment of Head Injuries."

Members of the Broome County Dental Society were invited to the meeting.

At the request of the State Society, Dr. E. R. Dickson, county society president, has appointed a subcommittee on the "Hard of Hearing and the Deaf." Members are Dr. Hiram Randall, chairman, Dr. J. D. Bowen, and Dr. Windsor R. Smith.

Cattaraugus County

The county society bestowed a life membership upon Dr. A. W. Smallman, Ellicottville, the oldest practicing physician in the county, at their meeting in the Olean House, Olean, on January 22. Dr. Smallman has been practicing medicine for fifty-four years and is widely known throughout that region.

Cayuga County

Delaware County

See page 464 for postgraduate lectures.

Erie County

"Stated Meetings [of the society] are yours and your problems should be discussed and decisions made in the Stated Meetings inasmuch as the society does represent the medical profession. This is much better than sitting around in the staff rooms offering criticisms and suggestions, which result in no particular, definite action for your welfare or that of the society. . . .

"Your committees are always willing to help you or to listen to suggestions for the good of its members or the profession as a whole.

"I am firmly convinced that the profession should take the *offensive* instead of the defensive which has been our habit in years gone by . . .

"We must keep the practice of medicine free from politics. We must insist always on free choice of physician by the patient. We must maintain that precious doctor-patient relationship. We must keep the quality of the practice of medicine foremost and not let quantity take its place.

"As regards the faults of the profession—and we have some—it is my conviction that they are all the result of individual selfishness in that we

think of ourselves and our own convenience rather than the profession and the practice of medicine as a whole."—*Nelson Strohm, M.D., retiring president.*

Elsewhere in this issue (page 435) there is an item about the resolution adopted by the society at the January meeting in which the society pledged itself to encourage civilians to walk more. In offering the resolution Dr. Harry C. Guess cited the great use made by Germany of walking tours to build up civilian health. He added that, mentally, walking would be good, for it will give people at least twenty minutes for thought and reflection.

Dr. Harvey P. Hoffman in his inaugural address as president of the society stressed the challenge of the times to the medical profession: "We cannot fail! We must meet these stern facts with action."

Greene County

At the meeting in January Dr. William J. Hoffman, New York City, addressed the society on "Present Day Treatment of Cancer."

The Emergency Medical Committee of the Green County Defense Council, under the direction of Dr. M. H. Atkinson, chairman, is appealing to all citizens of Greene County to present themselves immediately to their family physician for immunization against smallpox and typhoid fever. The committee also feels it advisable to have all children inoculated against diphtheria.

The committee also feels there is a great possibility that if Greene County suddenly becomes the residence of a large number of refugees or evacuees from the metropolitan district there would be a great danger of disease being brought into the county.

The doctors of Greene County have agreed to do this work at a reduced fee in order that every person in the county can receive the benefits of this immunization.

Herkimer County

Dr. Byron G. Shults is the new president of the Herkimer Academy of Medicine succeeding Dr. Howard C. Murray.

Other officers are vice-president, Dr. James F. Gallo; second vice-president, Dr. D. F. Aloisio; secretary, Dr. Fred C. Devendorf; treasurer, Dr. Harold T. Golden; executive committee, Drs. Shults, Aloisio, James W. Graves, A. L. Fagan, and Murray.

Dr. Nicholas D. Lill, Dolgeville, gave a paper before the county society on February 10 at the Mohawk Valley Country Club in Herkimer. Dinner was served at 6:00 P.M. Clinical reports and presentation of specimens completed the program.

The pH Factor

Hydrogen ion concentrations favorable to growth of common organisms

The modern conception of corrective therapy in vaginal leukorrhea insists upon readjustment of the vaginal acidity to normal and consequent re-establishment of the normal bacterial flora.

FLORAQUIN

acts not only by destroying *Trichomonas Vaginalis* and other offending organisms, but also by encouraging the growth of the normal flora, replenishing depleted mucosal glycogen and readjusting vaginal acidity to a normal pH.

Floraquin contains the protozoacide, Diodoquin (5-7-diiodo-8-hydroxyquinoline), together with specially prepared anhydrous dextrose and lactose, adjusted by acidulation with boric acid to a hydrogen ion concentration which produces a normal pH of 3.8 to 4.4 when mixed with the vaginal secretions.

For Office Insufflation—

Floraquin Powder, bottles of 1-oz. and 8-oz.

For Home Routine—

Floraquin Tablets, boxes of 24 tablets.

of the United States held on February 12 at the Waldorf-Astoria, New York City, the following officers were elected for two years: president, Rear Admiral James C. Pryor, M.C., U. S. Navy (Retired), re-elected; vice-presidents, Colonel Howard W. Barker, U. S. Veterans Facility, re-elected; Colonel Charles M. Walson, M.C., U. S. Army, Surgeon Second Corps Area; secretary-treasurer, Colonel Samuel Adams Cohen, Med.-Res., U. S. Army.

Oneida County

A series of radio talks, Hints to Health Program, arranged by the Utica Academy of Medicine, has recently been concluded. They were: January 19—Dr. Ward W. Millias, "The Emotions as a Cause of Illness"; January 26—Dr. T. Douglas Kendrick, "Scientific Experiment and Medicine"; February 2—Dr. William F. Coxon, Jr., "Modern Anesthesia"; February 9—Dr. Walter F. Duggan, "The History of Spectacles"; and February 16—Dr. Lynn M. MacConnell, "The Story of Anesthesia."

Onondaga County

At the meeting of the society on February 3 Dr. Louis Gussow talked on "Discussion of Boeck's Sarcoid with Report of a Case." Discussion was opened by Drs. Carlton F. Potter and James G. Derr.

At the same meeting Dr. Eugene Boudreau spoke on "Psychosomatic Medicine; the Contribution of Shock Therapies, including Electro-Shock; Case Reports." Dr. Harry A. Steckel opened the discussion.

The subject, "Recent Advances in the Diagnosis and Treatment of Cancer of the Prostate," was presented to the county society on January 6 by Dr. Leo E. Gibson and discussed by Drs. T. F. Laurie and Robert Brewer. "This presents a new and rather hopeful outlook to patients suffering from inoperable carcinoma of the prostate," says the *Bulletin*. "By performing a bilateral orchidectomy and the administration of stilbestrol, the male hormone, which undoubtedly has a stimulatory effect on such a growth, is presumably eliminated.

"When metastasis occurs, there may be an increase in the serum acid phosphatase. This usually slowly returns to normal after orchidectomy and the administration of stilbestrol. A large proportion of these patients are distinctly benefited as shown by relief of pain, gain in weight, and even a disappearance of bone metastasis. The whole subject is so new and the results are so gratifying that it is too early to predict what it may finally lead to."

Dr. George B. Andrews presented a paper on "Insulin Allergy," which was discussed by Dr. W. A. Groat. The importance of continuing insulin in patients where it is distinctly indicated was stressed, and those who are sensitive to it should be desensitized in order that they may have the benefit of insulin therapy.

See page 464 for postgraduate lecture.

Oswego County

At the regular monthly meeting of the county society, held at the Fortnightly Club in Oswego on February 3, Dr. Frederick Wetherell of the

Syracuse University Medical College addressed the society on burns with special emphasis on treatment of shock caused by injuries of this nature.

"The majority of deaths from burns are caused by shock rather than the injury itself," Dr. Wetherell pointed out. "This may come on immediately or it may appear in later stages of the patient's confinement," he added, explaining the methods of treatment and the value of blood plasma in this type of medical work. According to reports of the American Medical Society, 60 per cent of the casualties at Pearl Harbor were attributed to burns.

Dr. Wetherell's topic was enlarged upon by a demonstration of the Hematocrit, a device for determining the approach and degree of shock in injuries, by Dr. C. K. Elder. The instrument is in use at the Oswego Hospital and is an invaluable aid to prescribing the proper type of treatment for shock, as Dr. Elder illustrated with several case histories.

Otsego County

Rotarians in Oneonta who heard Dr. George W. Mackenzie, Cooperstown, on February 5 are undoubtedly better informed on medical topics than they were prior to that date. Dr. Mackenzie's subject was "What is Next in Medicine?" but rather than prophesy he reviewed what had been happening in the wide field of medicine, pointing out that the time lag between the scientific developments of medicine and their general application to reduce illness is the principal challenge not alone to the medical profession but to the people of the whole world.

Of the "miracle drugs" he says: "This story of the sulfonamides is a fascinating one, first, because it was made possible by the painstaking experiments of the chemists. It is based on the methods of science; it is a fascinating story also because it illuminates a trait of the human mind.

"Several times in the course of development of the sulfonamides an individual had staring him in the face a discovery of great importance but failed to appreciate the significance of what was before him. Third, the story is fascinating because the doctor now actually does sometimes see miracles. Patients who formerly would have been doomed to die now, not infrequently, are rapidly cured and restored to health.

"We may well ask: 'What next in the sulfonamides?' Almost certainly we shall have new sulfonamide drugs. Perhaps some of them will be better than those we have now. Already we know that fully 25,000 people in this country will survive pneumonia each year who formerly would have died.* We may well ask: 'What next in other fields of medicine?'"

See page 464 for postgraduate lectures.

Queens County

The borough president of Queens has proclaimed March 9-16 as Nutrition Week in connection with an educational campaign of the county society to teach consumers what to eat in war time to preserve their health.

The society, with the help of the auxiliary

1942 ANNUAL MEETING

of the

Medical Society of
the State of
New York

*Waldorf-Astoria
New York City*

April 27, 28, 29, 30

[Continued from page 468]

and the Queens Council for Social Agencies has been at work some time in drawing up a country-wide program of nutrition education.

Nutrition Week will be launched March 9 with a meeting in the Medical Society Building in Forest Hills, at which experts in the field of dietetics will speak. The following day there will be a symposium for professional social service workers so that they in turn can instruct those with whom they come in contact.

A nutrition exhibit also will be set up at the medical building, with a lecture on hand each day to explain the various subjects.

Rensselaer County

At the county medical society meeting, which was held in the Hendrick Hudson Hotel in Troy on February 10, Dr. Charles H. Wheeler, assistant professor of clinical medicine at New York Medical College, spoke on the sulfonamides.

Dr. John O. Sibbald, president of the society, presided and Dr. C. J. Handron introduced the speaker.

Richmond County

The following are the newly elected officers of the county medical society: president, Dr. H. Lynn Halbert, Tompkinsville; vice-president, Dr. D. Vincent Catalano, West Brighton; secretary, Dr. William H. Barlow, St. George; treasurer, Dr. Curtis J. Becker, St. George.—*William H. Barlow, M.D., Secretary.*

Schenectady County

Dr. Judson B. Gilbert of Ellis Hospital addressed the county society on "New Developments in Cancer of the Prostate" on February 3 in the nurse's home auditorium at the hospital.

A business meeting preceded.

Dr. Walter Brown, radiologist of the Ellis Hospital, has left to begin a Fellowship in Internal Medicine at the Mayo Clinic in Rochester, Minnesota. His appointment began January 1, 1942, and is for three years.

Dr. C. E. Mitton has been appointed radiologist of the Ellis Hospital.

Suffolk County

A joint meeting of the Huntington Hospital and the county society was held on January 28. A symposium on hypertension was presented.

The following speakers participated: Dr. H. A. Schroeder, Rockefeller Institute, "Experimental Aspects"; Dr. H. O. Mosenthal, New York Post-Graduate Hospital, "Medical Aspects"; Dr. H. G. Bugbee, St. Luke's Hospital, "Urological Aspects"; Dr. I. P. Sobel, Lenox Hill Hospital, "In Children"; Dr. Carnes Weeks, New York Post-Graduate Hospital, "Neuro-Surgical Treatment."

During January the Huntington Hospital conducted a symposium on cardiovascular diseases including hypertension and the speakers were Dr. Emanuel Libman, Dr. Samuel Silbert, Dr. Benjamin Jablons, and Dr. Saul Samuels, all of New York City.

Dr. Morris R. Keen was chairman of the program committee.

Dr. George M. Lott, director of the Division of Mental Hygiene, Suffolk County Health Department, has an article in the February *News Letter* on "Mental Hygiene in the Present Emergency." After reviewing the experiences as related by an English psychiatrist he concludes with this news of his locality:

The Mental Hygiene Division of the Suffolk County Department of Health is focusing its clinical and educational activities on the formative phases of character development. To this end as much work as possible is being done with parents, teachers, and school children. The early years are a critical period in everyone's health history. The correction of physical and emotional defects at this time enables the child to face school and social competition without handicap and makes for sound health later on. Permitted to stand, many of the trivial disorders of childhood develop into chronic or impaired capacity in adult life.

Westchester County

At the January meeting it was announced during the business session that the entire savings fund of the society is to be invested in Defense Bonds, and the special committee on medical preparedness under the chairmanship of Dr. Erich H. Restin, Mount Vernon, who is also chief of emergency medical service of the County Defense Council, announced that the society has assisted the county and local defense councils in perfecting medical services against all emergencies.

In this issue see pages 400 and 471.

INDUSTRIAL ACCIDENTS IN N. Y. STATE

The number of industrial accidents by years is a fairly accurate barometer of employment or lack of employment. For example, the total dropped 10 per cent the first year after the crash and at the peak of the depression years had dropped about twenty-five per cent.

From then on there has been a steady increase in the number of industrial accidents until the year 1940 it was again equivalent to the total in 1929.

Fatal accidents, however, in the plants of New York State after a decided drop following the crash, have decided to stay down. For the past eight years fatal accidents have been around 1300 to 1400 as compared to some 2,000 in peak prosperity years.

This may mean that better safety measures are being taken, although the total number of all types of industrial accidents does not indicate such improvement. And while fatal accidents show such a satisfactory reduction, permanent disabilities have continued to increase right through the years of unemployment.

If there is any reason for the lower mortality rate in industrial accidents it can well be that we have had some improvement in medical attention and technique. Even though this may mean that the injured worker has been saved from death only to survive with a permanent disability, still it is an achievement that, next to eliminating the hazard entirely, can be viewed with considerable satisfaction.

OUR TRANSIENT POPULATION DECREASES

In 1940, over 130 million persons entered and left the City of New York on trains and ferries alone. This is the equivalent of one visit by every man, woman and child in the United States. In addition, of course, there were countless more who used motor cars and buses exclusively.

Commuting included in the above figure comprises over 91 million of the total visits and 182,684,185 trips in and out of the city. However, this was almost 14 million less trips than in 1939 which in turn had over 4 million less commuter trips than 1938.

Apparently commuting is on the wane, but what is largely responsible for the steady reduction is not clear. The change in 1940 may be due to a shift in industry because of defense work, but the reduction in 1939 appears a little early for such a cause.

Ferries carrying privately owned vehicles seemed to fare better with a slight increase. In 1940, total traffic on such ferries reached 14,125,941 as compared with 14,029,673 in 1939. However, other privately owned ferries reported a reduction of passengers from 27,812,879 in 1939 to 24,010,536 in 1940.

Persons using the vehicle tunnels and bridges in 1940 were 13,328,803 in the Holland Tunnel; 3,900,000 in the Lincoln Tunnel; 8,455,000 over the George Washington Bridge; 696,000 over the Goethels; 370,000 over the Outer Bridge Crossing; and 638,000 over the Bayonne Bridge.

Hospital News

Hospitals in New York City Are Ready. . .

IF an emergency were to arise at this very moment, 2,000 cases, at least, could be accommodated, according to Dr. Edward Bernecker, of the Department of Hospitals, chief of the Emergency Medical Service, New York City. In a published interview in the current *Modern Hospital* Dr. Bernecker summarizes the defense preparations that are being made by hospitals in the New York City area.

He says that the number 2,000 will be raised to 5,000 and more when all existing facilities are organized and greater coordination of the various defense units has been accomplished.

Emergency medical field units, made up according to the Medical Division Bulletins of the Office of Civilian Defense, are a part of eighty city and voluntary hospitals. These units are directed to predetermined spots near the scene of the disaster for the treatment of minor injuries. Those in charge of these casualty stations must decide which cases should be sent to the hospitals.*

Dr. Bernecker says that one of the biggest problems facing the New York hospitals is the realignment of their staffs owing to the demands of the government upon the medical profession. With interns having only one year of training and with the elimination of residents it is necessary that the attending staffs assume new responsibilities.

Another readjustment that hospitals must make is the elimination of intern service on ambulances.† [This went into effect on all ambulance services of city hospitals in New York City on February 16. Qualified emergency first aiders are replacing the interns. It is expected that private hospitals will inaugurate the change in a few weeks.]

The realignment of duties follows on through nurses and voluntary nursing aids, graduate nurses assuming duties previously performed by doctors and the nursing aids doing some of the work of the nurses. Dr. Bernecker estimates that 1,000 women have been trained for these posts but that the quota calls for approximately 10,000.

Dr. Bernecker concludes with the advice that "Safe and Sane Defense" might be a slogan for every institution, but he does not recommend that hospitals go to extremes in preparing themselves for possible air raids or disaster from sabotage. He points out that while, at present, it is ridiculous to abandon the use of operating rooms on top floors it is equally foolish not to protect all skylights adequately. He added that every hospital should provide for an emergency operating room lower down in the building or on the first floor and that it would be well to rear-

range space allotments, where possible, to provide ward facilities adjoining these emergency operating rooms.

To administrators of hospitals Dr. Bernecker says that they should know their institutions as never before, not counting on assistants for certain knowledge . . . and, as executive officers in charge, they should be ready for call at any time.

Newsy Notes

Twenty-three physicians and surgeons deemed to have contributed most toward the creation of Polyclinic Hospital were honored on February 10 when their portraits were unveiled in the faculty room of the hospital which is located at 341 West Fiftieth Street, New York City. Seven of the honored men are living. They are Drs. Bryson Delavan, Bernard Sachs, Frederick Whiting, Charles G. Kerley, Orrin S. Wightman, Frederick H. Dillingham, and Royal Whitman.

. . . .

Dr. Bernard S. Oppenheimer was recently honored by his fellow physicians of the Mount Sinai Hospital, New York City, when he was presented an 869-page volume of medical papers. It is Volume VIII, Number 5 of the *Journal of the Mount Sinai Hospital*, consisting of 106 papers especially contributed for the occasion. Among the authors of these papers are many of the leading medical men of America, not a few of whom began their careers as Dr. Oppenheimer's pupils.

The hospital is celebrating its ninetieth year of service.

. . . .

Four hundred leaders of the medical profession attended a dinner on February 7 at the Waldorf-Astoria Hotel dedicating the recently opened Adelphi Hospital in Brooklyn. Dr. Thomas A. McGoldrick, chief medical officer in charge of civilian defense of Kings County, said the responsibilities of the new hospital at Greene Avenue and Adelphia Street were greater than had been anticipated because of its location near the Navy Yard, where thousands of men are working.

. . . .

Mrs. Edmond Borgia Butler, director of the Corps of Volunteers of St. Vincent's Hospital, New York City, has laid down three crisp rules for the 100 women who work under her.

"Know your place, find your place, and keep your place," she advises each recruit.

The volunteer service at the hospital is reputed to be outstandingly good.

. . . .

With the addition of about 25,000 subscribers and dependents last year, the Rochester Hos-

"QUICKIE" VACATIONS—AND WHAT NEXT?

If there is anything wrong with this country at present,
it is not that we are too complacent about the war but
rather that as a whole we are too inconsistent.

On one hand we have the boosters of greater efforts in
defense work and on the other hand those preaching
vacations. We are told to put more push behind the
machinery of industry—to take more vacations so we
can keep healthy and strong enough to bear the strain of
increased hours of work and increased tension.

Now comes the "Quickie" vacation so you or your
overworked patient can take short relaxation periods
with a minimum loss of time from work.

Gone are the days of "leisurely" spent vacations.
Now if Mr. Average Man can get away from work at
high speed, he is advised to rest "at high speed." Yet
there is something sensible back of it all.

We were always inclined to spend more time getting
to a place of rest and back again than actually in resting.
If we can shorten the transportation time, and the air
lines certainly have helped us this way, then surely we
can lengthen the hours of relaxation.

Just as we have come to know concentrated foods, so
it appears we may yet come to understand "concentrated"
vacation benefits.

pital Service Corporation boasts a membership of about 185,000, Sherman Meech, director, has announced.

The per capita rating of the association to the territory it covers is one of the largest in the country, Meech said.

His report coincided with an announcement by the American Hospital Association Hospital Service Plan Commission showing that 2,500,000 persons became members of associations in the nation last year, bringing the total membership to 8,500,000.

. . .

"The Alumni Association of the Jewish Memorial Hospital of New York City announces, with great pleasure, the appointment of Dr. Philip Slater, as roentgenologist of the Sea View Hospital."

. . .

In a building erected as a memorial to Queens men who served in World War I, Jamaica Hospital passed its fiftieth milestone girding for World War II.

On February 17—exactly a half-century since the charter for the hospital was granted—a dinner-dance was held in the Waldorf-Astoria Hotel, Manhattan. The celebration, however, was but a respite from the serious business of preparing to handle casualties that might come to Queens from enemy air attacks.

Fifty years ago the hospital opened its first building—a frame house with 5 beds at Jamaica Avenue and 168th Street.

. . .

Conferences with laymen and physicians of Harlem to discuss establishment of a voluntary hospital in that community have been in progress for some time, the third annual report of the Hospital Council of Greater New York discloses. The council is a community agency to improve hospital and health services throughout the city.

Such an institution, the report sets forth, would afford staff affiliations for qualified Negro physicians and accommodations for their private patients and additional ward beds for indigent patients.

. . .

"Wake up and forget Pearl Harbor," was the advice given by Dr. Ralph W. Sockman, pastor of Christ Methodist Church, New York City, at the recent annual dinner meeting of the Vassar Brothers' Hospital in Poughkeepsie. "Forget the vindictive, vengeful slogan, 'Remember Pearl Harbor,' and substitute for it a remembrance of the valiant defense of Wake Island," he urged. "We can win without the vengeance motive, win the war and win the peace to come after it."

. . .

Superintendents and superintendents of nurses in hospitals of seven counties in central and northern New York met in Broadacres Sanator-

ium, Utica, January 15, to discuss the part to be played by the institutions during blackouts and in event of emergency service resulting from air raids. Represented were the five hospitals in Utica, Ilion Hospital, Little Falls Hospital, Memorial Hospital in Herkimer, Pine Crest Sanatorium at Salisbury Center.

Also, Lowville Hospital, Oneida City Hospital, Rome City Hospital, Oneida County Hospital at Rome, Rome State School, Utica State Hospital, Mercy State Hospital, Good Samaritan Hospital in Watertown, and Broadacres Sanatorium.

Improvements

The capacity for patient care of Mount Vernon Hospital's x-ray department has been increased 75 per cent by the installation of new equipment at a cost of \$6,000 according to Arthur B. Solon, superintendent.

. . .

Action of the Office of Production Management in Washington listing the new St. Mary's Hospital in Rochester a "defense project," with a preference rating of A-4, has cleared the way for a financial campaign with a goal of \$275,000 which was held January 23-February 2.

The new hospital will aid powerfully in meeting what health experts term Rochester's greatest need in the field of health, supplying low-cost hospital beds for patients suffering from acute illness.

. . .

A \$22,000 extension that will increase accommodations by 17 beds will be constructed at the Saranac General Hospital.

. . .

To the welfare of the sick in peace or war, Archbishop Francis J. Spellman on January 4, dedicated a new nine-story building constructed as the major part of a \$1,300,000 modernization program at St. Vincent's Hospital.

. . .

Formal opening of the new extension of the Westchester Square Hospital, Seddon Street and St. Raymond Avenue was held on January 20.

The addition provides space for 110 beds and 30 bassinets, which increases materially the hospital facilities of the North Bronx section. The hospital, although privately operated, will continue its policy of taking care of emergency needs of the neighborhood, Dr. John Dolan, president, announced.

. . .

With the skyscrapers of lower Manhattan and their 1,000,000 working occupants particularly subject to enemy air attacks, plans have been made for setting up emergency facilities in Beekman Hospital and for raising \$500,000 to cover the cost.

"QUICKIE" VACATIONS—AND WHAT NEXT?

If there is anything wrong with this country at present, it is not that we are too complacent about the war but rather that as a whole we are too inconsistent.

On one hand we have the boosters of greater efforts in defense work and on the other hand those preaching vacations. We are told to put more push behind the machinery of industry—to take more vacations so we can keep healthy and strong enough to bear the strain of increased hours of work and increased tension.

Now comes the "Quickie" vacation so you or your overworked patient can take short relaxation periods with a minimum loss of time from work.

Gone are the days of "leisurely" spent vacations. Now if Mr. Average Man can get away from work at high speed, he is advised to rest "at high speed." Yet there is something sensible back of it all.

We were always inclined to spend more time getting to a place of rest and back again than actually in resting. If we can shorten the transportation time, and the air lines certainly have helped us this way, then surely we can lengthen the hours of relaxation.

Just as we have come to know concentrated foods, so it appears we may yet come to understand "concentrated" vacation benefits.

FALKIRK IN THE RAMAPOs

A sanitarium devoted exclusively to the individual treatment of MENTAL CASES. Falkirk has been recommended by the members of the medical profession for half a century.

Woman's Auxiliary

To the Medical Society of the State of New York

A REPORT of the Executive Board meeting held February 16-17, 1942, at the DeWitt Clinton Hotel, Albany, will appear in the March 15 issue of the JOURNAL.

Also watch for more State Convention News. The dates: April 27, 28, 29, 30, 1942. The place: The Waldorf-Astoria, New York City.

The following is a list of the chairmen of the Convention committees:

Mrs. L. E. VAN KLEECK—*Cochairman*
Acknowledgments, Mrs. S. W. S. TOMS
Dinner, Mrs. L. M. LALLY
Entertainment, Mrs. C. POTTER
Flowers, Mrs. F. E. ELLIOT
Headquarters, Mrs. L. HARRIS
Hobby Show, Mrs. H. L. HIRSCH
Hospitality, Mrs. B. D. ST. JOHN
House of Delegates, Mrs. W. J. LAVELLE
Information, Mrs. M. SCHULTZ
Junior Ushers, Mrs. F. TOWNE
Luncheon, Mrs. J. McKEEVER
Printing, Mrs. GEORGE SMITH
Publicity, Mrs. E. A. GRIFFIN
Registration of Delegates, Mrs. W. DAVIS
Registration—General, Mrs. H. MENCKEN
Resolutions, Mrs. A. M. BELL
Supplies, Mrs. OTTO PFAFF
Tea—Wednesday, Mrs. WM. CARHART
Tickets, Mrs. M. BERGMAN
Finance, Mrs. D. J. SWAN

These women are busy building the foundation for your convention. Please remember, sister members, we are counting on your help in the completion of its structure. More news in the next JOURNAL.

Be seeing you at the convention.

MABEL A. POHLMANN

County News

Cattaraugus. At a luncheon meeting in the Colonial Room of the Olean House an instructive talk on "Blood and Plasma" was given by Dr. David J. Maloney, who illustrated his topic. The membership decided to continue to have physical check-ups once a year.

Chautauqua. The wives of the doctors were entertained at the Eighth District meeting. Mrs. George B. Adams, state president, stressed the permanent value of the organization. The ladies joined the doctors for luncheon, after which they were taken on a tour of the furniture building, a rare privilege for guests. Afternoon tea at the home of Dr. and Mrs. Harold A. Blaisdell completed the afternoon plans. At the previous meeting the members were conducted by Dr. F. R. Weedon on a visit to the Municipal Laboratory.

Columbia. To the business meeting and luncheon at the General Worth Hotel, Hudson, January 27, each member was privileged to invite two guests. The guest speaker was Henry James, chairman of the Columbia County Red Cross Chapter.

A decision was made to assist Dr. Ralph Spencer in the cancer control program. A donation of \$10 was given to the Red Cross War Fund Drive.

Fulton. At the last meeting Mrs. Alfred Madden, state legislative chairman was guest speaker. The topic was "What Physicians' Wives Can Do in the State Program of Medicine." After the meeting the members did Red Cross work.

Montgomery. Mrs. George B. Adams, of Auburn, president of the New York State Auxiliary, was guest speaker at the monthly meeting which was held at the Town House. Preceding the meeting a luncheon was served. Mrs. E. A. Bogdan reported that it will be possible to place the *Hygeia* in the junior and senior high schools of the city and county. There was no February meeting. The next meeting will be on the second Monday in March.

Nassau. The auxiliary sponsored a nutrition forum. In March they are having a Cancer Institute.

Oneida. The outstanding project of the auxiliary for the year is "blood typing." Within the group there are two first-aid units, one the advanced.

Onondaga. A general plan of defense work is being carried on. At the last meeting Mrs. James R. Wilson gave an outline on "Organized Housewives." The March meeting will be an heirloom party. In April, Dr. Louis H. Bauer will speak on "Nutrition."

Oswego. The auxiliary gave a \$50 donation to the Red Cross, the proceeds from the fashion show. Mrs. Porter Butts gave an informative talk on the defense program.

Queens. Mrs. Alfred Madden was guest speaker at the January meeting. A donation was given to the Red Cross War Fund Drive. The amount was \$10.

Rensselaer. The last meeting was held at the McKean House of the Leonard Hospital. Mrs. Eugene F. Connally was elected president, succeeding Mrs. John J. Rainey. Mrs. Arthur W. Benson was made president-elect. The regular annual reports were given. Tea and a delightful party followed the meeting.

HOSPITALS IN NEW YORK STATE

According to the most recently released official figures on number of hospitals, New York State has 571 with a total bed capacity of 188,985 and 8,286 bassinets.

A recent edition of a hospital directory lists only 492 for the State but classifies them as: 346 General, 36 Mental, 34 Tuberculosis, 21 Obstetric, 12 Children's, 11 Prison, 8 Contagious, 5 Eye, Ear, Nose and Throat, 4 Convalescents, 3 Chronic Cases, 2 Incurables, 1 Nervous and Neurotic, 1 Special Type, and 8 unclassified.

As to ownership, the directory listed them as—181 by non-profit associations, 72 by churches, 52 corporation owned or controlled, 43 by cities, 33 by the State, 28 by counties, 27 by individuals, 14 by the Federal Government, 4 by partnerships, 2 by fraternities and 9 were unclassified.

In other words 118 were maintained by taxes, 255 are maintained purely on a samaritan basis, and 83 for commercial reasons—yet all serve a common and necessary need.

TWO HUNDRED YEARS AFTER

In 1975, two hundred years after the shot that was heard around the world—we will be an old nation in years and an old nation in population.

According to the Census Bureau's estimate, in that year of the future with a total population of some 152,000,000 beings, only 19.4 per cent of the population will be youths 14 years of age or less. Today this age period constitutes 25.1 per cent of the nation.

RECEIVED

Administrative Medicine. Haven Emerson, M.D., Editor. Quarto of 839 pages, illustrated. (Loose-leaf.) New York, Thomas Nelson & Sons, 1941. Cloth, \$7.50.

Dr. Haven Emerson has done a good job in bringing together in one volume a description of the various organized medical and community health activities in operation today.

It is a far cry from the simple forms of the private practice of medicine which prevailed for several generations to the present complex interrelations of private practice, disease control and health promotion.

More than fifty men and women, each qualified and active in his or her special field, have contributed to the subject matter set forth. The author divides the book into three fundamental parts, as follows:

1. The Organized Care of the Sick. Hospitals predominate in this group and all types are discussed, general, rural, communicable diseases, tuberculosis, mental, chronic diseases, and convalescent. The more recent developments such as organized medical care in the home through social service and by visiting nurses are considered next. Sickness surveys and voluntary hospital care insurance complete this group.

2. Public Health Services. Several sections are given over to the administrative features of governmental health agencies of various kinds. Then follow more than a score of functional activities, each discussed in a separate section.

3. Inclusive Medical Care for Prevention and Treatment. Under this rather vague heading, various medical services operating under governmental auspices in the armed forces and at colleges and universities are described.

It would seem that in this third group the modern community work done by county medical societies as units might be included. Again, those phases of industrial health work as administered in large and medium-sized corporations might have been given more attention as their work constitutes a major factor in this field.

Fortunately, the loose-leaf type of book selected for this publication will permit an early inclusion of subject matter that is lacking or the replacement of material becoming obsolete. And that is an admirable feature of this book.

ALFRED E. SHIPLEY

Outlines of Industrial Medical Practice. By Howard E. Collier, M.D. Octavo of 440 pages. Baltimore, Williams & Wilkins Company, 1941. Cloth, \$5.00.

The author states that the work was originally designed for a textbook of industrial medicine but that the relevant material was published in a modified and curtailed form as an *Outline of Industrial Medical Practice*, a statement that fully describes the book.

The work is divided into five parts. In Part

I the author describes the executive duties of the physician in industry, activities that have to do with organization of the first-aid room or dispensary, the application of first aid, and the care of the injured workmen, medical examinations, records, and statistics.

Part II deals with industrial hygiene, which the author classifies under advisory functions, and under this heading he treats ventilation, lighting, the effects of noise, speed of work, weight lifting, and motion at work.

Part III is devoted to industrial psychology, which the author deems is of importance, and under this title he includes the occupational neuroses and miners' nystagmus.

Part IV, Industrial Medicine, is devoted to a description of industrial poisons; the skin diseases of occupation; the pneumoconiosis; the effects of gases, smoke fumes, and toxic dusts; and the infections and the traumatic diseases of occupation.

Part V discusses the British Factory Act (labor laws in the United States) and also the application of the British Workmen's Compensation Act. There is a bibliography of six pages and an index.

The book is written in an interesting manner but is from the point of view of an English physician and British industrial life which the American physician, as a rule, has difficulty in understanding, since processes and occupations often have names not familiar in American industrial life. However, the author's treatment of the subjects—executive duties, industrial hygiene, diseases incidental to occupation, and industrial psychology—is for a small volume quite comprehensive and would be of aid to physicians in the United States who are engaged in the practice of industrial medicine.

CHARLES T. GRAHAM-ROGERS

Cardiac Clinics. A Mayo Clinic Monograph. By Frederick A. Willis, M.D. Octavo of 276 pages, illustrated. St. Louis, C. V. Mosby Company, 1941. Cloth, \$4.00.

This monograph is a compilation of the Cardiac Clinics published by the author in the weekly publication of the staff meetings of the Mayo Clinic. The subject matter is uniquely presented insofar as each cardiac symptom is discussed with a case in point to illustrate the desired clinical feature.

The cases are presented briefly and concisely, and the discussion is pointed after a style that characterizes all the author's publications. The arrhythmias are well presented. There are few but well-selected photographic illustrations. The book is written primarily for the busy practitioner and is, therefore, depleted of investigational data and all but the most pertinent facts.

It makes light reading and is well worth the effort. It should have a definite place in the library of every general practitioner.

NUMBER 6

Editorial

Immunization Urged

The vast program of production now under way in the war effort will necessitate enormous shifts in population. Crowded housing conditions and overtaxing of sanitary facilities in many communities must inevitably afford opportunity for the spread of communicable disease.

Anticipating this possibility, Assemblyman Lee B. Mailler, chairman of the New York State Health and Preparedness Commission, has set up an Immunization Committee in that body. The personnel is composed of Dr. E. S. Godfrey, Jr., New York State Commissioner of Health; Dr. Claude C. Pierce, medical director, U. S. Public Health Service; and Dr. John L. Rice, commissioner, New York City Department of Health.¹

"The Immunization Committee was organized to study and make recommendations regarding widespread immunization procedures to be instituted for the protection of the public from the standpoint of civilian defense and possible evacuation.

"Another disease [in addition to smallpox] against which the committee recommends vaccination is diphtheria. Particular efforts should be made to obtain the immunization of a larger percentage of children under 9 years of age. This should include all children under that age who have not previously been immunized, with particular emphasis on those less than 5 years old.

"The committee points out that while it is obvious that provision should be made for ample stocks of typhoid vaccine the primary emphasis in the prevention of typhoid fever should be placed on proper sanitation of environment, which would include the safety of water, the pasteurization of milk, and safe sewage disposal systems.

"The committee refused to recommend vaccination against other diseases for which specific vaccines of varying efficacy exist. It was stated that to include these diseases would detract from the effectiveness of efforts made to secure immunity against those diseases for which reliable and highly effective immunizing agents exist and whose prevalence in this country constitutes immediate and constant health hazard."

The principal emphasis in the organization of the medical aspects of civilian defense so far has been rightly placed on the hospitals and their ancillary services in order that they might function efficiently in the event of civilian catastrophes. But it must not be forgotten that the ordinary, as well as the extraordinary, functions of medical practice, health, and sanitation must go on.

Smallpox, diphtheria, and typhoid we have with us always. Parents can be enlisted in a more vigorous program of immunization of their children if each physician will stress the fact that in this way they can make a contribution to the betterment of the national health in a crucial period of our existence.

School physicians, school nurses, and local health departments should ma-

¹ Defense Digest, Defense Information Commission of the New York State Council of Defense, February 15, 1942, page 4.

terially assist the private practitioners by an active campaign of education directed to this end. The shortage of physicians and nurses now making itself felt throughout the state is an additional

reason for striking hard at this time to prevent the occurrence and spread of communicable disease. An ounce of prevention is, more than ever, worth a pound of cure.

Early Deficiency States

Much attention is being paid to the subject of nutrition by government, the profession, and the laity. Some of it is well directed. Of the rest, the less said the better.

It is probable that early nutritional failure is somewhat prevalent in the nation. Early deficiency states are difficult to recognize even by well-trained observers. Since it is not known how widespread these may be, it is difficult to assay the value of much of the present teaching in nutrition.

The current report of the subcommittee on Medical Nutrition, Division of Medical Sciences, National Research Council, is therefore of exceptional value at this time. Commenting editorially on the report published in the *J.A.M.A.* for February 21, 1942, . . .

"The Subcommittee warns that no symptoms or physical signs can be accepted as diagnostic of early nutritional failure. It says, however, that symptoms and signs 'when verified by a competent physician and when other possible causes have been ruled out should be considered as significant indications.'

"Those symptoms in infants and children which parents or teachers might observe are as follows: lack of appetite, failure to eat adequate breakfast, failure to gain steadily in weight, aversion to normal play, chronic diarrhea, inability to sit, pain on sitting and standing, poor sleeping habits, backwardness in school, repeated respiratory infection, ab-

normal intolerance of light, and abnormal discharge of tears. The physical signs are bad posture and sores at angles of the mouth.

"The symptoms in adolescents and in adults are as follows: lack of appetite, lassitude and chronic fatigue, loss of weight, lack of mental application, loss of strength, history of sore mouth or tongue, chronic diarrhea, nervousness and irritability, burning or pricking of skin, abnormal intolerance of light, burning or itching of eyes, abnormal discharge of tears, muscle and joint pains, muscle cramps, and sore bleeding gums. Sores at the corner of the mouth are the only physical signs listed in adolescents and adults which might be observed by laymen."

A careful reading of the symptoms and signs will indicate the difficulty in making a clinical diagnosis of early deficiency states and emphasizes the warning of the subcommittee. Physicians will do well to call to the attention of teachers the medical facts of the subcommittee's admonition. Most of the defense councils now in operation have a committee on nutrition. It is composed of lay people in most places. As these become active and attention is drawn to possible instances of early deficiency states, physicians will be consulted by anxious parents. It is well that they should bear in mind the fact that no acceptable diagnostic criteria exist and that a diagnosis should be made only when all other causes have been ruled out.

Buy U. S. Defense Bonds and Stamps

Industrial Health in Wartime

On February 26, 1942, the Committee on Public Health and Education of your Society, through the Subcommittee on Industrial Health, presented its first program at Buffalo, New York, under the auspices of the Medical Society of the County of Erie, the University of Buffalo School of Medicine, the Division of Industrial Hygiene, New York State Department of Labor, and the New York State Department of Health.

Under the chairmanship of Dr. Herbert H. Bauckus, a program including industrial pulmonary diseases, technics of physical examinations in industry and medical standards for rejection, systemic effects of various substances commonly used in industry, traumatic surgery with emphasis on the treatment of wounds and shock was presented by a distinguished group of industrial physicians and surgeons.

The membership of six interested adjacent county societies was invited to attend as well as third- and fourth-year medical students of the University of Buffalo School of Medicine. Industrial organizations and the local Chamber of Commerce together with other interested civic groups proved to be most cooperative.

Industrial medical personnel in this period of wartime speedup is needed in three principal fields according to the *J.A.M.A.* for February 21, 1942: "(1) the government services, (2) governmentally owned but privately operated ordnance works, and (3) private plants with war contracts. . . . Under the pressure of events neither employers nor physicians yet fully comprehend how vast a contribution could be made to the war effort by a well organized industrial health program. . . .

"Medical organizations, in company with trade and manufacturing associations, are beginning to undertake the dual obligation of educating industry to the benefits of modern industrial health and developing physicians able to respond to

this created demand for medical supervision. The process must be accelerated lest some form of compulsory medical supervision be imposed on industry, as has already occurred in England. The ability to bring the physician into the plant under terms agreeable to industry, to the worker and to medicine will be enhanced if suitable education and promotion can be developed."

Certainly the first program of the Committee on Industrial Health is a step forward in the promotion and implementing of such a well-organized endeavor as that called for by the Council on Industrial Health of the *A.M.A.* We hope this is the first of a series that will eventually cover the entire state. At the same time some forethought must be given to the practical issue of the reservation of especially trained personnel. A contribution to this problem is offered by the *J.A.M.A.*

"If a substantial demand is created, much will depend on the ability of the Procurement and Assignment Service to avoid the dislocation of the existing supply of competent industrial physicians who are doing an essential job of keeping indispensable men at work. A physician under 45 who is physically fit and who wishes to remain in his industrial position would need to be certified as absolutely essential to industry by the industrial establishment which employs him. Industrial physicians in the 45 to 60 age groups might be dislocated if certain specialist classifications should be called. In the over 60 group, dislocation is considered unlikely. New medical personnel for industry will be located and assigned under advice from corps area, state and county referees, with the assistance of the Procurement Board's Advisory Committee on Industrial Health and Medicine. As substitutes for eligible and replaceable industrial physicians, principal reliance will no doubt be placed on physically unfit male physicians under 45."

Since the percentage of rejections for full military duty in the age group 45 to 65 will undoubtedly be high, it would seem to us that a special appeal to this

group by the Society's Committee on Industrial Health to attend its educational courses in industrial hygiene would prove valuable. Through the services of the newly formed P. and A. state office

it should shortly become possible for the first time in this war for the Society to reach any particular group of physicians, thus increasing materially its postgraduate educational efficiency.

A Word to Our Authors

For those of you who are preparing to read a paper at the Annual Meeting, and which subsequently will be published in the JOURNAL, we are printing in this issue two pages of "suggestions." The one opposite deals primarily with the preparation of the manuscript which, if followed, will greatly expedite the publication of the paper. The suggestions on page 574 (if followed), will make the paper more enjoyable for its readers.

A word also to those discussing papers: often these remarks are given without preparation yet should be printed as a part of the program. For this reason, before the discussions are handed in, they should be prepared for publication with regard to typing, continuity, and brevity.

Papers that are often received enthusiastically at a meeting are not necessarily so satisfactory in print and, because of this fact, much care and thought should go into the preparation of a manuscript. "When the paper is published the personal equation does not enter in and the courtesy of the listener has vanished; it is now in cold type."¹

"Brevity, conciseness, the elimination of unnecessary details and the avoidance of branching off into unrelated and irrelevant subjects and of the use of colloquial language" should be the goal of authors.

Pardon our "preaching" but since you must be our readers as well as our authors the editors feel justified in making every effort to give you a still better JOURNAL.

¹ *Medical Writing*, A.M.A. Press.

Correspondence

To the Editor:

We have all heard about the number of "social gains" that should not be surrendered during the stress of war. One of the keystones of the program of "social gains" consists in what is called a standard work week. In certain trades "overtime pay" begins after thirty hours per week, and in some other occupations excess rate pay begins at forty hours a week. The sky is the limit as to the number of hours an individual may work on an overtime pay basis.

I realize that life is always full of iniquities, and that there is reasonably good evidence that artisans of various sorts engaged in defense production may be so much in demand just now that one should not envy the carpenter getting paid \$150 a week or an average pay check of from \$60 to \$100 a week for individuals who are qualified in semiskilled occupations.

It also happens that at the present time there is a shortage in the supply of physicians, and that the shortage is noticeable in certain special branches of medicine.

It is now obvious that physicians will materially increase their civic responsibilities and add to their quota of voluntary and unpaid work in hospitals. It seems to be true that physicians are going to be called upon to devote additional unpaid time to various preparedness and defense duties.

There is no reason to believe that revenue from private practice will materially increase for the physicians who remain on a civilian status. They may do more work but purchasing power impairment will be reflected in fees received.

The gist of all this is that physicians can hardly be put in the class of those who are profiting from the war or increasing their incomes in proportion to the increase in the number of hours per week spent in professional work.

Sincerely,
GEORGE H. HYSLOP, M.D.

February 12, 1942

If You Are Reading a Paper at the 1942 Annual Meeting . . .

THE NEW YORK STATE JOURNAL OF MEDICINE will appreciate your following the suggestions listed below in the preparation of your manuscripts. These suggestions have been devised in order to save correspondence, avoid return of papers for changes, minimize the work of preparation for the printer, and save the high costs of corrections made on galley proof.

Size of Articles.—It is earnestly desired that scientific articles shall not exceed ten JOURNAL pages at the outside. Even that number of pages tends to lower reader interest. An average of five or six seems to be the most desirable from this point of view. Calculation can readily be made by multiplying the number of double spaced typewritten manuscript pages by the fraction two-fifths.

Manuscripts.—Papers must be typewritten on one side only of white sheets consecutively numbered, and be double spaced with one-inch margins. They should be prepared with great care so as to be typographically correct. All headings, titles, subtitles, and subheadings should be typed flush with the left-hand margin.

Titles.—The title should be *brief* and typed in capital letters. The subtitle can be longer and should be typed in cap and lower case letters. Under the title, or subtitle, if there is one, should appear the name of the author and city in which he lives.

Subheadings.—Subheadings should be inserted by the author at appropriate intervals.

References.—It is the unfailing practice of the NEW YORK STATE JOURNAL OF MEDICINE to use specific "references" rather than "bibliography." There should appear in the text reference numbers, typed above and to the right of the word to which there is a reference. A list, consecutively numbered, should include the following items.

- a. *Books*—author's surname followed by initials; title of book; edition; location and name of publisher; year of publication; volume; and page number. Thus, Osler, W.: Modern Medicine, ed 3,

Philadelphia, Lea & Febiger, 1927, vol. 5, p. 57.

- b. *Periodicals*—author's surname followed by initials; name of periodical, volume, page, month (day if necessary), year of publication. Thus, Leahy, Leon J.: New York State J. Med. 40: 347 (Mar. 1) 1940.

NOTE: The JOURNAL does not include titles of articles.

Case Reports.—Instead of abstracts of hospital histories, authors should write these reports in a narrative style with properly completed sentences. All unimportant details should be deleted with such general negative statements as fit the case.

Tables.—While tables are very useful on lantern slides in the reading of papers, they fail of this purpose to a large extent in the printed page. For that reason it is urged that they be incorporated in the text.

Illustrations.—These should be kept to the minimum necessary to make clear the points to be registered by the author. In some instances they are imperative to proper understanding, in others they are merely picturesque.

Where illustrations are to be used they should accompany manuscripts and each should always be referred to in the text, preferably by number. Drawings or graphs should not be larger than 12 × 16 inches, and must be made with jet black India ink on white paper or tracing cloth. *Do not use typewriter for lettering.* The smallest lettering on 8 × 10 inch copy should be no less than 1/4 inch high. Cross-section paper (white with black lines) may be used, but should not have more than 4 lines per inch. If finer ruled paper is used, the major division lines should be drawn in with black ink, omitting the finer divisions. In the case of finely ruled paper, only blue-lined paper can be accepted. Lettering and all markings must be large enough to be readable after reduction. Mail rolled or flat. Photographs should have clear black and white contrasts and be on glossy white paper.

Whenever possible "crop" photographs, i.e., mark portion that can be excluded when reproduced. Crop marks should be on *margin* of photographs—not on the photographs.

It is important to mark the top of the illustration on the back, also its number as referred to in the text, thus, Fig. 1, 2, and the name and address of the author.

Legends should be typewritten on one sheet of paper and attached to the illustrations.

House of Delegates—Reference Committees

THE Speaker, Dr. Louis H. Bauer, announces the appointment of the reference committees or the meeting, April 27, 1942.

Symposium on the Mortality of Amputations for Diabetic Gangrene

DIABETIC LOWER EXTREMITY AMPUTATIONS

A Report Over a Five-Year Period at St. Luke's Hospital

FRED W. SOLLEY, M.D., New York City

THE following is a statistical study of all types of amputation involving the lower extremity in diabetic patients admitted to the wards at St. Luke's Hospital during the five-year period from 1934 to 1938, inclusive. In order to evaluate properly the results of such a survey, a brief general outline of the methods used in handling these cases seems desirable.

Outpatient Department

The medical diabetic clinic is exceedingly satisfactory, being well organized under the direction of Dr. James Ralph Scott. It has surgical and orthopaedic consultants in regular attendance, as well as a podiatrist who has attended the clinic for over five years under both medical and surgical supervision.

The outpatient department surgical care of the diabetic patient is fair, being handled by the general surgical clinic. It is chiefly a matter of luck whether the patient is seen by a surgeon who is particularly interested or experienced in "diabetic surgery."

The follow-up is managed by the general surgical follow-up clinic, and each surgeon usually sees the cases upon which he has operated.

Hospital Care

The actual surgery is done by any surgeon on the attending staff, since there is no real specialization. Medical consultations, when requested, are excellent as to cooperation and judgment, but here, also, any medical attendant may be called, since there is no actual organized teamwork. More recently, and especially since the period covered in this case report, the attempt has been made to insure experienced consultations for diabetic patients, both medical and surgical, with gratifying improvement in our results.

Anesthesia is in no way specialized for the diabetic patient. Each surgeon selects the anesthetic he desires at the time of operation. All anesthetics are given by resident physicians specializing in this work, and not infrequently decision as to the type of anesthesia for a given

diabetic case is left to the anesthetist. Personally, I believe anesthesia for these cases to be in the following order of desirability: (1) low spinal (with inhalation of oxygen as needed), (2) cyclopropane (or ethylene) and oxygen, (3) nitrous-oxide and oxygen, (4) ether added to the above gases, (5) open ether, (6) local novocain (rarely useful except for the incision and drainage of a well-localized superficial abscess), (7) chloroform—never!

Preoperative preparation of the extremity is usually done by the attending surgeon, or under his supervision by the resident, after the anesthesia has been started.

As a rule, tincture of iodine is applied to the skin and then partially removed with alcohol, but recently the various proprietary mercurial tinctures are gaining popularity.

Chemotherapy was not used in this series either before or after operation, and none was used locally in any of the wounds.

Operative technic is naturally variable, since the cases are handled by so many different surgeons. Some apply tourniquets; others do not. In the closed amputations most operators use catgut in the muscles and fascial layers and silk or dermal in the skin.

Pre- and postoperative medications also vary greatly. Morphine and hyoscine are the "routine" preoperative drugs and, recently, the barbiturics, especially sodium pentobarbital, are frequently added.

Our indications for amputations depend upon two factors: adequacy of circulation and severity of infection. Oscillometric and dermo-thermic readings are not routinely used, and in my humble opinion these facilities are entirely unnecessary in arriving at an accurate and reliable decision as to the indication for amputation. Experienced and intelligent use of the time-proved methods of inspection and palpation are sufficient. The circulation is considered "adequate" if the patient shows: (1) a warm foot with or without a palpable dorsalis pedis pulsation; (2) little or no pain on bed rest for twenty-four to forty-eight hours with adequate diabetic treatment.

Severity of infection is determined by:

1. Obvious presence of cellulitis or abscess formation, as well as x-ray evidence of suppurative arthritis or osteomyelitis. Incidentally,

Symposium read at The New York Academy of Medicine under the auspices of the Committee on Surgery of the New York Diabetes Association, Inc., December, 13, 1940.

TABLE 1.—INCIDENCE OF DIABETES AND GENERAL DIABETIC SURGERY (FIVE-YEAR PERIOD—1934 TO 1938, INCLUSIVE)

	Hospital Admissions	Total Diabetic Patients*		Total Surgical Diabetic Patients	
		Cases	Per-centage	Cases	Per-centage
Five-year total	39,370	702	1.8	258	0.7
Yearly average	7,874	140	1.8	52	0.7

* Percentage of general surgery in total number of diabetic patients is 36.8.

the presence of incipient suppurative arthritis or osteomyelitis can and should frequently be detected clinically before any x-ray evidence of these lesions can be demonstrated.

2. Fever is the most valuable evidence to us of the severity and seriousness of the infection. White blood counts and sedimentation tests are helpful, but in the last analysis the fever tells the story. With a rectal temperature persisting over 101 F. for more than forty-eight hours on bed rest and adequate diabetic treatment, we seriously consider an emergency amputation. And with cool or cold toes or foot, pain on bed rest, and a temperature over 101 F. leg or thigh amputation is considered imperative.

The site of amputation is determined by applying the same criteria. "Conservative" amputation of a toe and the distal part of its metatarsal, as long advocated by McKittrick, is performed in those cases with adequate circulation and an infection sufficiently mild or well localized to justify the procedure.

When the circulation is judged to be inadequate by the presence of cold and painful toes and foot, a "closed" leg or thigh amputation is performed provided the infection is mild or well localized as evidenced by a low temperature.

With inadequate circulation and severe infection shown by high fever, guillotine amputation in the leg or thigh is performed.

The Gritti-Stokes has been used to some extent in our hospital, but in my opinion this plastic operation on the knee joint requires such adequate circulation that a leg amputation below the knee would be equally successful in any case where it is worth consideration, with the obvious advantage of a preserved knee joint.

Dressings following these amputations vary considerably, as would be expected from the foregoing. The usual closed amputation is covered with a dry dressing, and a protective posterior molded plaster splint is frequently added. In guillotine amputations, moleskin or adhesive skin traction is the rule, with wet dressings or ointments applied to the wound as seems indicated. Clean wounds are left unmolested for six to ten days. Open or drained cases are dressed daily or every second day. The early postoperative dressings are usually done by the attending surgeon, who in many cases prefers to do all the dressings himself. If the dressings are done by interns, supervision is at regular

TABLE 2.—ADMISSIONS REQUIRING AMPUTATION, SINGLE OR MULTIPLE (1934 TO 1938, INCLUSIVE)

Total Deaths Mortality	34* 9 26.5%
------------------------	-------------------

* Actual number of patients—30. Four of these had two different admissions for amputations.

intervals, and in our experience this is important.

Nursing care of the surgical diabetic is in no way specialized in the hospital and, although the nurses are given the usual special training relative to the medical diabetic patient, all special care of the surgical condition requires special instruction, supervision, and orders for each particular case.

The foregoing regimen pertained to the five-year period covered in this review of the records. During the four years following, the desirability of specialization has been fully realized and, with its gradual adoption, gratifying improvement is becoming evident in our results.

In this five-year period, the total number of hospital admissions, the number of patients with diabetes, and the number of these diabetic patients who were subjected to general surgery of any kind are shown in Table 1. That over one-third of the diabetic patients underwent some form of operation seems remarkable, especially when we realize that before the advent of insulin a patient with diabetes was almost universally regarded as a dangerous risk for surgery.

Analysis of the series as to whether the diabetes was known to the patient and, if so, whether it was adequately treated revealed the following: admitted in total ignorance of their diabetes, 9 per cent; knew of the diabetes but had no treatment, 9 per cent; treated by diet but no insulin, 33 per cent.

Henceforth, this analysis is confined to diabetic patients on the ward services who underwent some form of amputation of the lower extremity. The total number of separate admissions of such cases in this five-year period was thirty-four, but the actual number of patients thus represented was only 30 as 4 members of the group were admitted twice. The mortality was 26.5 per cent, as shown in Table 2.

The sex incidence in this series seems worthy of mention. There were twice as many women as men—66.6 per cent women. Moreover, of the patients who died, 7 out of the 9 were women—77.8 per cent woman preponderance. Such figures serve to emphasize the damage done by the all too prevalent toe-

TABLE 3.—ANALYSIS OF MORTALITY AS TO SITE OF AMPUTATION

	No. of Cases	Deaths	Mortality, Percentage
Toe or toes only	9	0	0
Total leg amputations	7	3	42.9
Gritti-Stokes	6	1	16.7
Knee disarticulation	1	1	100
Thigh	11	4	36.3

squeezing feminine shoe—a frequent cause of discomfort or disability in the normal woman but far too often the inciting cause of death in the diabetic.

Age incidence was about average for these cases. The oldest patient was 74; the youngest, 45; and the general average, 62.

An analysis of the mortality as to the site of amputation is shown in Table 3. The absence of a single death in the group where toe amputation alone was done gives a false impression as to the safety of this procedure. In this series, in all cases where toe amputation alone did not control the infection, a leg or thigh amputation was subsequently performed. In behalf of conservatism, however, it is worthy of note that 9 patients, 26 per cent of the cases, were successfully treated by toe amputation alone.

The mortality in reference to multiple amputations is shown in Table 4, which strongly emphasizes the danger in allowing conservatism to overshadow proper regard for the safety of the life of the patient.

Of the 9 deaths in this series, 4 of the patients had preliminary toe amputations that were unsuccessful in controlling the infection and were followed later by amputations at a higher level. This is shown by the complete analysis of our mortality which is covered in Table 5.

Length of postoperative hospitalization, given in days with reference to the site of amputation, was as follows: toes only—average, 55.3, shortest, 13, longest, 150; legs—average, 36.3, shortest, 19, longest, 68; Gritti-Stokes—average, 36.4, shortest, 21, longest, 62; and thighs—average, 42.7, shortest, 26, longest, 73.

Analysis of the histories as to the type of injury which led to the amputation revealed the following: (1) shoe pressure on corn, 10 cases; (2) walking on plantar callus, 4; (3) patient cut corn, 4; (4) soft corn removed by chiropodist, 1; (5) infection and gangrene, cause unknown, 6; (6) dry gangrene, cause unknown, 3; and (7) accidental injuries (no one to blame)—(a) "injury to foot" (unspecified), (b) dropped pail on foot, (c) foot was

TABLE 4.—MORTALITY ANALYSIS AS TO MULTIPLE AMPUTATIONS

	No. of Cases	Deaths	Mortality, Percentage
Toe or toes followed by leg, knee, or thigh	8	4	50
Toe or toes followed by leg	2	1	50
Toe or toes followed by Gritti-Stokes	1	0	0
Leg amputation followed by thigh	2	0	0
Toe or toes followed by thigh	5	3	60

stepped upon by someone, (d) burned toe soaking feet in hot water, (e) accidentally scratched dorsum of foot, (f) went to sleep with electric pad on foot.

In an endeavor to ascertain to what extent the beds on supposedly "active" ward services are "tied up" by these cases, the following was elicited: (a) Of the patients who lived, the grand total of days in the hospital was 1,763 days; the longest hospital stay, 210 days; the shortest hospital stay,* 13 days. (b) Of the patients who died, the grand total was 270 days, the longest hospital stay, 66 days; the shortest hospital stay, 4 days.

The financial loss to the hospital in this series of cases (ward cases only) was: average cost per patient per day, \$6.75; daily average paid by patients, \$1.81; average loss to hospital per patient per day, \$4.94; loss in this series from patients who lived, \$8,709.22; loss in this series from those who died, \$1,335.80. The hospital loss from the total number of patients in the series was \$10,045.02.

Follow-up Results

Of the cases who survived, those wearing artificial limbs were as follows:

Out of 4 patients with leg amputations, 1 wore a prosthesis. There were 5 patients with Gritti-Stokes' amputations who survived; 2 of them wore prostheses. Of 7 cases surviving thigh amputations, none wore an artificial limb.

The reasons given for not wearing a prosthesis were as follows:

* Such a short hospitalization following any amputation in a diabetic lower extremity seems worthy of mention. The case was one of dry gangrene without any evidence of infection, appearing spontaneously in one toe of a diabetic woman who had remarkably good circulation in both feet. This in itself was unusual and was probably some localized vascular accident. The toe was amputated by disarticulation at the metatarsophalangeal joint, and the wound was closed by suture without drainage. The wound healed by primary union and her total hospital stay was thirteen days! We have never seen this happen before or since, and we certainly do not recommend it as a good procedure in these cases.

TABLE 5.—MORTALITY ANALYSIS AS TO CAUSE OF DEATH

Case	Sex	Site and Nature of Lesion	Age	Diabetes controlled	Preoperative		Circulation in Extremity	Amputations	Hospital Cause of Death	Days Lived Postoperative	Adequacy of Surgery
					General condition	Surgical risk					
1	F	Ulcer, fourth toe with cellulitis	64	Severe and uncontrolled	Very toxic; temperature, 104 to 105	Poor on admission	Very good	1. Toe and metatarsal 2. Closed thigh	Cardiac	1	Fair surgery (killed by delayed admission)
2	F	Infection and gangrene of third toe	67	Moderate	Temperature and pulse normal (arteriosclerosis)	Good	Very bad; cold foot and much pain	1. Toe and metatarsal 2. Upper third of leg (closed)	Infection and gangrene of stump (myocarditis and arteriosclerosis)	24	Poor judgment in both operations
3	F	Infection and gangrene of second toe	65	Mild	Temperature, 104; very toxic; acidosis; chronic cardiac valvular disease	Poor	Poor; cool foot and some pain	1. Toe and metatarsal 2. Closed thigh	"Toxemia" and chronic cardiac valvular disease	10	Ill advised; needed primary thigh and probably guilotine instead of toe amputation
4	F	Ulcer through plantar callus	70	Severe	Temperature and pulse normal	Poor	Fair; toes cool; foot warm, and pain slight	Upper third of leg	Cerebral thrombosis	23	Good. Temperature normal until nineteenth day postoperatively. Stump seemed to be clean and healing well
5	F	Infection and gangrene of fourth toe	60	Moderate	Nontoxic; pancytopenia and decompensation	Very bad	Bad; cold foot and much pain	Closed knee disarticulation	Infection and gangrene in stump (cardiac decompensation)	24	Fair. Thigh amputation would seem to have been wiser
6	F	Gangrene, third toe, and cellulitis of foot	55	Mild	Toxic; temperature, 101; nephritis. Chronic cardiac valvular disease	Bad	Bad; cold foot and marked pain	Upper third of leg (closed)	Uremia, cardiac decompensation; late gangrene of stump	17	Fair. Thigh amputation would seem to have been wiser
7	M	Gangrene of toes extending to foot	59	Mild	Temperature, 103; very toxic; bad cardiac	Bad	Bad; foot and leg cold and much pain	Lower thigh, very loosely closed	Arteriosclerosis and myocarditis	12	Excellent
8	M	Infected fissure, fourth web	61	Mild	Temperature and pulse normal; bad coronary (electrocardiogram)	Bad	Poor; cool toes and marked pain	Gritti-Stokes	Coronary occlusion (proved by electrocardiogram pre- and post-operatively)	4	Good
9	F	Ulcer, dorsum of foot	74	Mild	Temperature and pulse normal; bad chronic cardiac valvular disease	Bad	Poor; toes cool and some pain	1. Toe and metatarsal 2. Lower third thigh, loosely closed	B and panaritium and decompensation	2	The amputation was followed by spreading infection (debridement or thigh amputation would seem to have been wiser)

Amputation Site	Too Feeble	Simply Would Not Wear It	Other Leg Off
Leg (below the knee)	1	1	1
Gritti-Stokes	2		1
Thigh	5	1	1

The length of follow-up is: followed to time of death, 7 cases; went back to family physician, 3; failed to come ("lost"), 4; followed for a time then lost—two years, 2, one year, 2, and six months, 1; and transferred to chronic homes, 2.

A survey of the longevity of these cases revealed the following: 1, aged 66, died one year later; 1, aged 67, died two and one-half years later; 1, aged 70, died six months later; 1, aged 69, died three years later; and 1, aged 59, died three years later.

The value of chemotherapy has been so definitely established during the past two years that its employment in foot or leg infections in diabetic patients is becoming al-

most a routine. Though not used in this series of cases, we have employed it subsequently with increasing regularity, and the valuable assistance it offers in controlling infection, safeguarding conservative surgery, and reducing mortality makes it indispensable in the modern care of these patients.

Conclusion

The importance of specialization in the surgical care of the diabetic lower extremity cannot be overestimated. Equally important is the closest cooperation between the physician and surgeon. Hospital reports, showing striking reduction in mortality when such organization has been adopted, offer unquestionable evidence of the advantages to be gained by any institution able and willing to so specialize. It was in the hope of stimulating the desire for better surgical care of the diabetic lower extremity in all hospitals, as well as our own, that the analysis of these cases was undertaken.

SURGICAL ASPECTS OF DIABETIC GANGRENE

FRANCIS MCGARVEY DONEHUE, M.D., New York City

IN THE five-year period of 1935 to 1939, inclusive, 479 patients with diabetes were admitted to the Lenox Hill Hospital, of which only 21 proved to have surgical conditions: in 19, the lower extremity was affected; in 2, the upper extremity.

Source

Referred by outside doctors or on personal application	19
Referred from the outpatient department	2
Eleven different surgeons of the staff treated these 21 cases.	

Site of Involvement

Left foot	12
Right foot	7
Right hand	2
The little toe was most frequently involved in the left and right feet.	

Vascular Aspects

(a) Dorsopedal pulse:	
Absent	10
Present	4
Not mentioned	5
(b) Hypertension—present	2

Bacteriology

(a) Cultures

Associate surgeon, Lenox Hill Hospital
Lieutenant Commander, M.C., U. S. N.

Staphylococcus aureus	3
Staph. aureus (hemolytic)	5
Streptococcus (hemolytic)	3
(b) Blood culture positive only once (a hemolytic streptococcus), other cultures were negative.	

Anesthesia for Amputations (Toes and Thighs)

Spinal	6
Gas, oxygen and ether	10
Cyclopropane	3

Roentgenologic Findings

(a) Calcification of vessels (3 or 4 plus)	16
(b) Calcification of vessels, unreported	5
(c) Osteomyelitis	6

Amputations

- (a) *Indication:* rapidly ascending infection, lacking localization in the foot.
(b) *Site:* lower or middle third of thigh, leg amputation being considered too risky—i.e., unlikely to control ascending infection.

Thigh amputations (13)

	Number	Deaths
Lower third amputation	4	3
Midthigh	9	2
Toe amputations, single	9	0
Toe amputations, multiple	0	

Toe amputations followed by thigh amputations (3)

Two cases with no amputation were:

1. A septic patient who signed out against advice and
2. An aged woman with an absolutely uncontrollable diabetes.

(c) Types of amputation

	Number	Deaths
Guillotine	8	3
Flap	4	1*
Gritti-Stokes	1	1

(d) Drainage

	Number	Deaths
Drained	9	4
Not drained	3	1*

Secondary Operations (2)

1. Infected stump—died of pneumonia and nephritis;
2. Ligation of femoral artery for hemorrhage—death, subsequently, from sepsis.

Analysis of Depths (8)

(a) After thigh amputation	5
(b) After toe amputation	2
(c) After no operation (which was refused)	1

* Same case—a woman, aged 36, came late in her disease because of poor economic conditions. Marked atherosclerosis; flap operation. Died of pneumonia.

(A) Abstracts (After Thigh Amputation)

- (1) Atherosclerosis; nephritis; pneumonia.
- (2) Atherosclerosis (premature, age 36); sepsis; pneumonia.
- (3) Profound emaciation on admission with marked atherosclerosis; ligation of femoral artery for secondary hemorrhage—sepsis—death.
- (4) Amputation stump completely healed; hypertension; died of congestive heart failure.
- (5) Amputation stump completely healed; coronary occlusion.

(B) Abstracts (After Toe Amputation, 2)

- (1) Profound emaciation, sepsis of three weeks' duration; hemolytic Staph. aureus. No spread from foot, therefore, no thigh amputation indicated.
- (2) Great loss of weight on admission; only one toe amputated; diabetes never controlled in this aged, decrepit woman; complicating pyelitis; cellulitis; sepsis; death.

(C) Finally, a man with diabetic gangrene of one toe, who had a hemolytic streptococcus, blood-stream infection, refused surgery, and left against advice with blood culture still positive. This was the only patient who was not operated on and was the only case with positive blood culture.*

* It is unavoidable that the same cases come up again and again in the statistics on various aspects of this problem.

MEDICAL ASPECTS OF DIABETIC GANGRENE

EINAR GUSTAFSON, M.D., New York City

IN SURVEYING our 21 cases of diabetic gangrene from a purely medical aspect, several important facts are disclosed. In the majority of instances (19) these patients were first seen by the hospital staff after admission on the surgical wards. Hence, their chances were lessened, both medically and surgically, by one physician. Consequently, little or no knowledge either of the previous control or the cooperativeness of the patient were available, and in the final analysis these two factors are the most essential ones in the care of any diabetic case. The lack of these is obviously the downfall of most persons with diabetes. The obligation of the physician in educating his patient about his disease must be assumed. Unfortunately, this assumption is not always justified.

Aside from the problem of diabetic infection and gangrene, it must not be forgotten that diabetes is a systemic disease and must be

treated as such. The diabetic patient is afflicted with numerous other associated maladies. Coronary sclerosis develops from five to eight years earlier in diabetic than in non-diabetic patients. Weight loss, though only an indicator, has far more reaching significance. Ketosis, lowered resistance, avitaminosis, etc., frequently present themselves at the bedside. All these factors are of extreme importance to the surgeon, inasmuch as the operative risk is directly proportionate to their severity if present.

How much the financial or sociologic status reflects itself in the patients is difficult to say. One thing is certain, however; the majority of these patients were too poor to be strictly private cases and too rich to be classed as indigent. This in itself may be a factor in the present survey.

A more detailed analysis of some of the statistics in this limited series is as follows: number of cases—21; deaths—8, 38 per cent;

sex—15 women, 6 men; average age—60 years for all cases; average duration of known diabetes—six years and three months, a range of none to nineteen years; condition of diabetic patients on admission—uncontrolled in 13 cases and controlled in 8 cases.

The majority of cases, however, were well controlled on diet and regular insulin preoperatively. In cases in which emergency amputation was done because of the extent and type of the presenting lesion, preoperative infusion of saline and glucose buffered with insulin were given. Protamine insulin was not used in any case where either acute infection or postoperative course contraindicated it. In all surviving cases, the diabetes showed marked improvement postoperatively. In only 1 case could prolonged lack of control of the diabetes be attributed as the major cause of death. In several others we noted the associated maladies found in diabetic patients—namely, heart disease and cachexia, together with intercurrent pulmonary infections, which at the best are difficult to cope with in elderly individuals let alone in diabetic patients.

Interesting are the 2 cases of amputations of the toes which responded to extremely conservative measures. As a matter of fact, one of these had a readmission for a similar procedure on the other foot. I understand that now, five years later, his general and peripheral vascular conditions are under good control.

DIABETIC GANGRENE

Report of Cases Treated at Roosevelt Hospital, Five-Year Period, 1935 to 1939, Inclusive

GRANT P. PENNOYER, M.D., New York City

THE victim of diabetic gangrene is struggling against three distinct disease processes. Each one is present in varying degree and each accentuates the other two. The clinical picture and prognosis vary greatly with the severity of each process, and successful treatment depends on the control of each process.

First, there is the diabetes that may be so slight as not to manifest itself except in the presence of infection or so severe that its control becomes exceedingly difficult despite huge doses of insulin and accurate control of all intake.

Summary

Uncooperativeness and lack of control of their diabetes were the pitfalls of the majority of patients admitted to Lenox Hill Hospital for gangrene or infections of the lower extremities. Nail-cutting and self-treatment of a paronychia of the hand were responsible for 2 cases of osteomyelitis necessitating finger amputations. No such history of trauma was given in the other 19 cases. However, despite this, foot hygiene should be as much a part of the education of the diabetic individual as diet, insulin, etc., and in this the physician is probably more at fault than with regard to instructions about diet and insulin. Once gangrene has developed, conservative measures should be carried out to the fullest extent, using as a criterion the adequacy of the peripheral circulation. On the other hand, infection, when present, knows no barriers. Chemotherapy, though not used in these cases, is a great aid when used with discretion, bearing in mind that it is not a cure-all and that surgery must be done in certain cases before the infection becomes too widespread. When surgery is contemplated in these cases it usually is not the adequacy of the circulation that determines the site of amputation but rather the extent of the infection. These are surgical problems and should be treated as such. The mortality in these cases is not so much related to the local lesion as it is to the fact that we have a patient who is sick, generally.

Second, there is infection that may be minimal as in the case of the slow, dry, well-demarcated gangrene of the toes or so severe that despite adequate blood supply there is rapid wholesale destruction of tissue similar to gas gangrene and life is endangered by overwhelming sepsis. Third, there is the arterial occlusion, which varies in degree from slight to complete obstruction. It is always a local manifestation of a generalized arteriosclerosis which frequently has already affected the central nervous system, kidneys, eyes, and every other organ of the body, giving the patient a rather hopeless outlook for recovery of his

health before one considers the problem of the gangrene.

With three such variables present in every case, superimposed on the great difference in individuals, it is quite obvious that the clinical entity known as diabetic gangrene is going to have infinite variations and that no fixed rules of treatment are possible. Every case has to be considered strictly as an individual problem; each factor has to be evaluated and treated. That indefinable priceless gift, known as surgical judgment and based on experience and not found in the hospital laboratories or instruments of precision, must be used to the utmost.

First, there is the diabetes the rapid control of which is essential. At Roosevelt Hospital this problem is handled by consultation with one of the Medical Staff interested in diabetes and working in the Diabetic Clinic. Ideally, this man makes rounds with the surgeon, but this is a perfection that is not always possible and consultation notes are often used. Great credit is due the House Staff, for when the medical consultant arrives he frequently has little to suggest beyond what has already been done. These industrious men, in order to bring quickly a rampant diabetes under control, will frequently be up long hours in the night administering insulin according to repeated blood and urine analyses. There is no question that the control of the hyperglycemia is the first step in the treatment of diabetic gangrene.

The second problem is the arrest of the infection. The general surgical principles of the control of infection apply, such as absolute rest, wet dressings, adequate drainage, and chemotherapy. If severe spreading infection as evidenced by local signs, fever, and leukocytosis is superimposed on advanced arterial occlusion and uncontrolled diabetes, the problem is at its worst and prompt midhigh amputation is often necessary to save life. Such an infection causing a wet undemarcated gangrene in the presence of a violent diabetes, even without advanced arterial occlusion, may require emergency guillotine operation as a life-saving procedure, but in this group one should be able to save the knee joint. Such cases without advanced arterial occlusion may be extremely ill at the time, but they offer the best prognosis for future life and usefulness.

The third factor is the arterial occlusion. It is the dominant etiology of dry demarcated gangrene and is the factor over which we have the least control. In my experience, no medications, injections, surgical operation on the

sympathetic nerves, physical therapy, etc., are of any material value in increasing the arterial capacity of these patients. All one can do is to institute measures that allow the patient to conserve, for the nutrition of his tissues and control of infection, all the arterial supply of the foot.

If the patient's life is not threatened by infection and the gangrene will localize, I am very much on the side of conservative treatment. Those cases with advanced arterial disease are discouraging at best, for the process is almost always just one expression of an extensive generalized arteriosclerosis. If one extremity is amputated, it is frequently only a short time before trouble starts in the other leg or the patient is stricken with some other arterial accident in his heart, brain, kidneys, or eyes. After a major amputation is done they are frequently too feeble to use an artificial limb, and the patient becomes an invalid for the rest of his life. I have had many patients with diabetic gangrene, where the arterial occlusion was the dominant factor, who have healed after weeks or perhaps even months of treatment with only the loss of toes or parts of toes and have regained a considerable degree of activity and usefulness. Their life expectancy is short at best. A major amputation frequently completely discourages the patient, so he becomes a chronic invalid. To illustrate this, there were 3 cases that had previously lost toes on one side and, finally, required major amputation on the opposite side. All 3 had done fairly well until the amputation, after which they were all incapacitated. The argument that if the circulation of an extremity is so poor that gangrene has occurred the extremity will not heal and, if it does, the limb will be useless can easily be refuted by case reports. Many surgeons still recommend midhigh amputation in cases of gangrene confined to the toes. I consider this malpractice.

In the conservative treatment three principles are applied. The first is absolute rest. I quite realize that it is not desirable to keep elderly people in bed for long periods of time, but it is necessary for success in the conservative treatment of diabetic gangrene due to arterial obstruction. After the infection and diabetes have been controlled, healing depends on the circulation. Active muscles require many times more blood circulation than the basic nutrition of the tissues and wound healing. This is easily demonstrated by basal metabolism studies. Active use of the muscles of the lower extremity uses up most of the available blood supply before it reaches the

feet where the amount is already so reduced that the basic nutrition of the tissues is in danger. If a house has poor water pipes, one cannot get water on the top floor if the cellar outlets are wide open. Even Buerger's exercises, when they have to be done by the patient's own muscular energy, may do more harm than good. Muscular rest is essential to conserve all available blood supply for the feet.

Gravity has an appreciable effect on the circulation, and position is of some importance. If the ordinary bed is used, the head should be elevated so that the feet are considerably below heart level. The increase of venous pressure, as well as the dependent flow of the blood may be of some help. The Sanders bed is physiologically sound for the same reason.

The third principle in the conservative treatment of diabetic gangrene is the thermostatic control of the temperature of the involved extremity to about 92 F. This is the approximate temperature of the normal extremity. The feet in a case of advanced arterial occlusion are somewhat like a cold-blooded animal in that they assume the temperature of the environment and regulate their metabolism to that temperature. Keeping the temperature normal is simple and greatly contributes to the comfort and healing of these patients. If the temperature is higher than 92 F., the local metabolism is increased and there is an increase in the discrepancy between tissue demand and blood supply. Even a rise of 1 or 2 degrees may start a burning pain in the leg that has previously been perfectly comfortable. A diminution of the temperature below 90 F. brings in some element of vasospasm as the direct result of chilling and, likewise, leads to discomfort. It is not at all uncommon to have patients with gangrene who have been unable to sleep because of excessive pain, despite large doses of strong sedatives, rest comfortably without medication as soon as the thermostatic control to 92 F. in the bed cradle is instituted. I have seen this simple device straighten out many elderly people who were formerly completely exhausted by pain and depressed by excessive sedative medication. No hot-water bags, heating pads, baking machines, or any form of heat, even bed cradles with electric lights (unless thermostatically controlled) should ever be employed on these patients. In addition to causing pain, the danger of burning is great. The cutaneous sensation in severe cases is dull or completely absent, so that the patient has no warning of damage. In addition, there is no circulation to conduct away the heat. An intact circu-

lation will keep the skin cool in the presence of heat just as it will tend to keep it warm in the presence of cold. On this account, a temperature that may feel quite comfortable to the skin of the face may cause a severe burn if the circulation is arrested. In addition to the danger of burning, the heat may precipitate a gangrenous process by increasing the discrepancy between the blood demand and the blood supply.

In treating these cases conservatively it is imperative for success that one man, experienced and interested in this work, follow the case and do all of the surgery and dressings himself. In the presence of gangrene any operation is dangerous except simple incision for drainage proximal to the productive inflammatory area of the demarcation zone. This zone, like granulation tissue, is more resistant to infection than freshly incised tissues. It is safer not to perform any local amputation, sequestrectomy, removal of sloughs, etc., until the separation of the living and dead tissue is almost complete. This may take many weeks, but the gangrenous tissues can then be eased off through the demarcation zone without anesthetic and without danger. No other surgery is performed except simple incisions for drainage when necessary. Sloughs should be allowed to separate spontaneously. If a clean granulating base can be obtained, small full thickness skin grafts can be tried.

If amputation is essential, careful studies should be made of the circulation to determine the level. The pulse, the oscillometer, skin temperature reading, and the rate of absorption of saline wheals, are all useful. At Roosevelt Hospital the only question is whether to amputate above or below the knee. The foot, ankle, lower leg, and amputations, like Gritti-Stokes designed for end weight bearing, have been discarded. A good knee joint with a few inches of tibia permits the use of as simple and as effective a prosthesis as any amputation below this level and, likewise, a mid thigh amputation gives as good a result as any stump without the knee joint. It is extremely desirable to save the knee joint, and this can be done in many cases where the practice previously has been almost routinely a mid thigh amputation to insure sufficient circulation for proper wound healing. The follow-up of mid thigh amputation cases is extremely poor for return of activity.

Technic

The technic of the operation is all important for success. We are dealing with poorly nour-

* Three cases with thigh amputations and 2 with leg amputations had previously lost toes or parts of toes on opposite side.

ished tissues with infection in the lymphatics. Damaged or devitalized tissue is an invitation for infection, necrosis, and disaster. Undoubtedly, the least traumatizing operation to the tissues would be a straight guillotine with a sharp amputation knife. Because of the difficulty of handling the exposed bone and muscle that results we use a modified guillotine. I am opposed to any operation using skin flaps, as the first sign of trouble is usually along the edge of a skin

flap. A circular incision obviates this difficulty. This results in a scar over the end of the stump, but in a prosthesis not using end weight bearing this does no harm. The circular incision is carried right down through the skin, fat, and deep fascia with one continuous firm stroke of a sharp scalpel about 6 inches below the level selected for the division of the bone. Hacking of the tissues with repeated small strokes of the knife, dull instruments, and careless use of hemostats all cause unnecessary tissue damage. The principal nutrient arteries of the skin run in the deep layer of the superficial fascia and no skin flap should be raised from the deep fascia. All unnecessary trauma must be avoided, such as grasping the skin with forceps, rough blunt dissection, towel clips, etc. The muscles are divided straight across by sharp bold dissection, preferably with an amputation knife, about 3 inches above the skin incision level and the bone is divided about 3 inches higher. No tourniquet is applied because of the possibility of arterial damage and because it is important to know just how much arterial bleeding there is. If one knows the anatomy, the main vessels can be recognized and clamped immediately on division. If the amputation is through the tibia, the anterior subcutaneous border must be beveled sharply to avoid skin pressure at this point. The fibula should be shorter than the tibia for the same reason. It is not necessary to inject the nerve endings with alcohol, but the large nerves should be identified, stripped back, and divided as high as possible so that they will be well above the scar. With this simple precaution we have had no amputation neuromas or painful stumps. It is of paramount importance that not a single suture be placed in the muscle, fascia, or subcutaneous tissue. None is necessary. These muscles atrophy, as their action was on the joint below the one which has been amputated. Sutures exert pressure and interfere with the circulation. This process is further aggravated by postoperative edema. They also tend to close the fascial layers that should be left wide open for drainage. The loose skin is drawn together by 3 or 4 skin clips or sutures fully 1 to 2 inches apart. The skin edges should be long enough to come together almost naturally. This allows free drainage without the use of any irritating foreign body, such as rubber tissue, etc. The closure of the circular incision will leave a corner on each end of the wound. This is no cause for worry, as experience shows that the skin will soon conform to the shape of the stump and the end cosmetic result will be quite satisfactory. This operation provides almost as little tissue injury and as free drainage as a true guillotine operation and at the same time avoids the difficulties associated with exposed muscle and bone. The whole procedure can be done in less than twenty minutes, and there is a minimum of shock. The absence of sutures and tissue insult minimizes the postoperative pain. Many

of these cases drain a considerable amount of bloody serum for a few days and then heal up practically by primary union.

In the last six years we have had at Roosevelt Hospital the Vascular Clinic for the study and follow-up of cases of peripheral arterial occlusion, as well as an older Diabetic Clinic. These two clinics work together, and a glance at their statistics shows the great advantage of this arrangement. Not a single patient who has been treated in both these clinics before the onset of gangrene has come to a major surgical amputation. Prevention is by far the most important treatment of diabetic gangrene. The early recognition of the arterial disease and the control of the diabetes are the most valuable contributions of these clinics, for they permit the necessary measures to avoid trouble. After all, diabetic gangrene is an end result of these other disease processes and is not a primary condition. Simple measures, such as cleanliness, avoidance of all trauma, proper care of the feet and nails, orthopaedic shoes, abstinence from tobacco, etc., accomplish wonders. Those with amputations are a great object lesson to the others and frequently impress the patients with the importance of following instructions more than any other method. The Clinic also allows more accurate and complete follow-up of these patients.

Tables 1 and 2 summarize our experience and results of all the cases of diabetic gangrene (40) admitted to Roosevelt Hospital in the five-year period from 1935 to 1939, inclusive.

Discussion

Dr. Madge C. L. McGuinness, *New York City*—Twenty-four cases of peripheral vascular disease in diabetics were treated by physical therapy, representing one-fourth of all the peripheral vascular disease cases in the hospital. In the clinic, 22 cases of a total of 92 were likewise treated.

Of these, only those in the third and fourth stages will be discussed. These had ulceration, infection, osteomyelitis, and gangrene. All had, in addition to the diabetes, inadequate circulation, vasospasm, and general debility.

Three cases were scheduled for mid thigh amputation but fortunately escaped and walked out on their own feet. Two had incision and drainage, and 3 others had incision and drainage and osteotomy.

Three others who came to mid thigh amputation were advanced in years and in poor condition but came through the operation and are alive and declare themselves well. One other at the age of 72 escaped amputation, had incision and drainage with osteotomy, left the hospital,

TABLE 2.—RESULTS OF 40 CASES OF DIABETIC GANGRENE, ROOSEVELT HOSPITAL, 1935 TO 1939, INCLUSIVE

Total No. of Deaths in Hospital = 4 (10 per cent)	
1.	Man, aged 59, mild diabetic, advanced arterial occlusion. Previous hospital admissions. Had lost 2 toes. Mid thigh amputation after thirty days conservative treatment. Flap operation—rubber drains. Died suddenly twenty-four hours postoperative. Coronary occlusion?
2.	Woman, aged 67, severe diabetic, advanced arterial occlusion. Rapidly spreading infection and wet gangrene. Thigh amputation thirty-six hours after admission. Flap operation—rubber drains. Died on eighth day from infection.
3.	Man, aged 68, mild diabetic, advanced arterial occlusion. Had lost 2 toes already on opposite side. Mid thigh amputation after two months' conservative treatment. Flap operation—rubber drains. Wound failed to heal. Chronic infection; bed sores; became weaker; finally died twenty-one days postoperative with terminal pneumonia.
4.	Man, aged 62, severe diabetic with advanced arterial occlusion. Conservative treatment five weeks; upper leg amputation. Flap type—rubber drains. Died of infection fourth day postoperative. Temperature, 108 F.

Late Results of Thigh Amputations*

Total Number = 12

Died in hospital	3
Known to be dead since leaving hospital	5
Arteriosclerotic heart disease	1
Carcinoma of stomach	1
Arteriosclerotic psychosis	1
Gangrene and pneumonia	1
Cause unknown	1
Chronic invalids without prosthesis	3
Lost to recall	1

Late Results of Leg Amputations Below the Knee†

Total Number = 6

Died in the hospital from infection	1
Wearing prosthesis successfully (2 over 70 years old)	4
Chronic invalid without prosthesis yet (1 year)	1

Late Results of Cases Losing Only Toes or Parts of Toes

Total Number = 22

Hospital deaths	0
Foot healed and patient doing at least light work	10
Foot healed but unable to be active enough for any work	3
Foot healed but an invalid from other causes	2
Foot still unhealed	1
Died of coronary heart disease	1
Died in another hospital from gangrene	1
Lost to recall	4

* Not one successful result. Of course, these are the worst of the 40 cases. All of the hospital deaths had flap operations and rubber drains instead of modified guillotine.

† This illustrates the importance of conserving the knee joint if possible, but the fatal case might have been saved by thigh amputation.

but died months later of cerebral embolism. This prima donna was described as a "hellion" and so came rightly by her ailment and demise.

In addition to medical and surgical measures, the physical procedures used were rest, warm saline soaks and compresses for infections, careful drying with gauze between the toes with and without aristol, dry heat, the cradle with the light bulb set at 92 F. continuously. Invented originally by Dr. Isaac Starr, of Philadelphia, improved by Bierman, of New York, a special cradle was devised and perfected by Valverde; this is by far the greatest single help in these conditions. Intermittent venous occlusion, embodying Bier's venous hyperemia and Lewis' reactive arterial hyperemia with gentle pressure and a soft cuff, is applied for hours or continu-

ously; the pavex is applied rarely, when not contraindicated. Iontophoresis helped to heal ulcers and lessen pain; we prefer histamine because it is cheaper and less general in effect. For reflex dilatation we gave infrared and diathermy, long or short wave, to the abdomen in some severe cases.

The remainder of the cases that were adequately treated in time—as soon as any complication set in—are continuing to attend the office, hospital, or clinic. Under frequent supervision, they need no surgical assistance at present. Of close on 100 cases treated, none has come to amputation.

The Peripheral Vascular Disease Clinic, set up several years ago, consists of a medical chief, associates particularly interested in peripheral vascular diseases, the chief in physical medicine, and a surgeon. We place the surgeon last because we hope we won't be needing his services except when the others fail. He is our anchor to windward in desperate cases that we hope will soon be rare.

Before the clinic was established, cases were treated in the department of physical medicine, and the following routine was worked out with the cooperation of Dr. Anna Samuelson, who has faithfully taken care of the clinic cases, examined and helped with the medical care of hospital cases, checked records, and examined frequently these cases reported here and other cases with allied conditions. Skin temperatures, oscillographic readings, posterior tibial nerve blocks, and various tests were undertaken and careful records kept.

I. For purposes of treatment, cases were divided into six classes, as follows: (1) minor infection with no impairment of circulation; (2) minor infection plus impairment of circulation; (3) moderate infection, no impairment; (4) moderate infection, organic lesions; (5) extensive infection, no impairment; (6) extensive infection, organic lesions—(a) peripheral vascular disease only or, in addition, (b) cardiorenal vascular disease.

II. The patients were likewise divided into 2 groups—ambulatory or bedridden.

III. Treatment consisted of: (1) control of diabetes by diet and insulin, most important; (2) rest; (3) elevation.

IV. Warmth: (a) proper woolen clothes and stockings, shoes, blankets, etc.; (b) dry heat—(1) the vasculator, a cradle with a thermostatically controlled light unit set at 92 F. for continuous environmental temperature and (2) short-wave diathermy through the abdomen and pelvis for reflex dilatation; (c) wet heat, saline—(1) foot soaks for cleansing and drainage and (2) warm compresses for drainage.

V. Mild antiseptics as (a) potassium permanganate or plain saline foot soaks, (b) tincture of green soap to loosen detritus, (c) carefully dried, etc.

VI. Inunctions, as lanolin, to keep skin soft.

VII. Proper fitting footwear to prevent corns and calluses.

VIII. Correction of orthopaedic defects—posture, body mechanics, etc.

IX. Care of corns and calluses (hygiene of feet) by physicians.

X. Medications: (a) acetylsalicylic acid, 5 grains three times a day, for vasodilatation; (b) phenobarbital, $\frac{1}{2}$ or $\frac{1}{4}$ grain three times a day, for sedation; (c) whiskey, wine, beer, once or twice daily; (d) calcium gluconate, 5 grains three times a day; (e) saline by mouth; (f) pancreatic tissue extract injections, 2 or 3 cc. three times weekly; (g) vitamins A, B, C, and D; (h) iontophoresis—histamine or acetyl-beta-choline for peripheral dilatation, of which the former is cheaper and has less general effect.

Mechanical aids include: (a) the vasculator (cradle with light bulb at 92 F. continuously); (b) intermittent venous occlusion which exerts a gentle pressure with an air cuff at timed intervals for several hours daily in chronic cases or continuously in acute cases; (c) the pavex is rarely applied, because infection or too great pressure from the cuff or from suction contraindicates its use; (d) iontophoresis, histamine, or acetyl-beta-choline; (e) infrared or diathermy, long or short wave, to the abdomen for reflex dilatation.

Smoking is absolutely forbidden.

Surgery as indicated: (a) incision and drainage; (b) sequestrotomy; (c) amputation of toe(s), foot, knee, or mid thigh.

Exercises, Buerger's and modifications of them, only when permissible.

Prevention

To watch these patients with peripheral vascular disease and listen to their stories, one is overwhelmed with a desire to do something to prevent augmentation of this ever increasing army of sufferers. It is a problem for all medical practitioners and especially for the general medical man who, as usual, sees all the headaches first and must do something for them before they progress to an early invalidism.

Diabetes is always a potential hazard and should be controlled at every cost. Diet is, of course, the first consideration, with or without insulin.

Rest is the next greatest essential and cannot be too greatly stressed. Relaxation comes next to mind. Worry, tension, and fatigue are much to be deprecated; we must forget them in our efforts to be well.

Warmth is also one of the first thoughts in peripheral vascular disease—warm clothing, warm socks, warm stockings, warm bedclothes, warm rooms. Whatever you may be able to do in this line with the miserable men who take to wool socks and mittens without a murmur, I wish you joy trying to get the suffering sisters to adopt anything but two-thread or nylon

stockings, which they solemnly assure you they have *always* worn.

Those "economic royalists" in the upper brackets, whose creditors still permit them to seek the sun in Florida, California, and the Southwest, can help themselves to an equable climate, with no weather, to the benefit of their circulation with no further ado, or, they can hug the firesides in their air-conditioned homes and laugh at wintry blasts.

Their brethren in the lowest brackets, the well-publicized 33 $\frac{1}{3}$ per cent engaged in the questionable process of shadow-living, can hug *their stoves* and let the mailman expose *his* extremities to the biting blast that plays such havoc with cramped blood vessels until such times as warm and sunny days tempt them forth to amusement.

But for those who must bear the burden of the workaday world, some means must be found to prevent this miserable diseased state that is threatening to fill our hospitals and homes with

ailing invalids losing the power to stand or walk.

For these, carefully regulated, properly conditioned rooms with heat, humidity, and no draughts must be provided in hospitals, convalescent homes, hotels, and apartments for hours at a time or continuously in severe weather.

It is useless to argue about warmth or order it if we permit these people to sit for hours in cold, draughty corridors in clinics awaiting attention. They should be instructed to stay home in inclement weather and to be out only on sunny days and between the hours of 10:00 A.M. and 1:00 P.M.

With proper care of the feet, all foot ailments corrected by physicians who are not above caring for corns, calluses, ingrown toe nails, etc., we will have less need for amputations and less fear of fatal results and this disease also will take its place with the others that are being overcome in the good fight waged by medicine in every field.

INFECTION AND GANGRENE OF THE LOWER EXTREMITY IN DIABETES MELLITUS

HERBERT CONWAY, M.D., and STEPHEN C. MEIGHER, M.D., New York City

THE management of amputation of an extremity has demanded the attention of those interested in surgery since there have been operations on humans. Amputation in ancient periods was accomplished by nature, without surgical intervention. Amputation by surgery to accelerate the rate of healing and the usefulness of the remaining stump undoubtedly was practiced in those ancient periods of which there exists no accurate surgical record. As a lifesaving procedure, amputation is heralded with genuine appreciation. Because this operative procedure represents an admission of failure to cure an extremity of its disease, it is looked upon with disfavor. In war and in peace, amputation of an extremity presents itself as a method to be avoided if possible, but it is one that must be carried out with strict attention to the many details involved to the end that more men may live usefully and happily for a longer period of time. As an important portion of the surgery of geriatrics, thrust upon the surgical world by the fact that today there is an increased percentage of the population living in the advanced age decades, rightfully, the surgery of amputations is receiving emphasis.

This presentation is limited to a statistical

study of a group of patients of one type encountered in civil surgery—namely, the group exhibiting infection and gangrene of the lower extremity in association with diabetes. It is a commentary on present-day surgery that local measures to prevent the development of gangrene have not been expanded and practiced generally to keep abreast of the splendid forward developments in the fields of endocrine therapy and chemotherapy, developments now known to be indispensable in the management of the complications exhibited by the diabetic patient. This analysis of experiences with gangrene of the lower extremity in diabetic patients on the Surgical Service of the New York Hospital is presented in conjunction with similar reports from three other institutions of New York City—St. Luke's, Roosevelt, and Lenox Hill hospitals. It is a pleasure to make this presentation because it affords an opportunity to analyze critically the results that have been obtained and to compare them with those of the other groups of cases.

The data that are presented concern the clinical course of 46 diabetic patients suffering from gangrene of the lower extremity. These were managed on the Surgical Service of the New York Hospital between September, 1932, and March, 1940. In that same period of time 774 diabetic inpatients were treated on

the Medical and Surgical services while 1,791 diabetic outpatients were treated in the dispensary. Although not all of the 46 cases had their prehospital treatment in the dispensary of the New York Hospital, the relation between the two figures 46 and 1,791 gives some idea of the probability of occurrence of gangrene in diabetic patients. This proportion is 1 to 40 or 2.5 per cent. Of the patients admitted to the hospital, those with gangrene of the lower extremity made up 5.9 per cent or, roughly, 1 in 16.

Information concerning age, sex, and religion of the 46 patients is as follows:

Age Group	Number of Patients
40-50	4
50-60	15
60-70	22
70-80	4
80-90	1
Total	46

The average age of 62.1 years is somewhat higher than that reported by others who have called attention to the fact that gangrene of the extremity occurs more frequently in the younger age decades in the diabetic than in nondiabetic subjects. It would appear from this analysis that the local condition of gangrene of the leg in diabetes occurs in advanced adult life chiefly between the ages of 50 and 70 years, since 37 of 46 patients were within these limits at the onset of their local condition.

There were 23 men and 23 women, of which 10 were Jewish (21.7 per cent), 21 were Catholic (45.6 per cent), and 15 Protestant (32.6 per cent). All of the 46 patients in this series were Caucasian.

An interesting fact brought out in the study of the histories of the cases is that 25, or 56.5 per cent, had passed from active physical life to inactivity in the period of one to six months preceding admission to the hospital for the care of the leg. Twenty patients, or 43 per cent, gave the history that the local condition came on while they were engaged in ordinary healthful activity. The importance of this change from active to inactive life is one that cannot be minimized. It suggests at once that those diabetic patients who have any complaints referable to the peripheral vascular bed should substitute peripheral vascular exercises for their usual activities during periods of relative quiet. Unfortunately, as will be brought out later, many of these patients have no peripheral vascular

symptoms until the onset of the local condition that leads to the development of gangrene of the extremity. Then, too, the increased hazard of complete daily activity with its inevitable trauma to the feet must be considered as a state predisposing to the development of gangrene, especially in the aged who may be unmindful of diminished peripheral perception of touch, heat and cold.

In 22, or 47.8 per cent, of the cases the records show significant loss in weight in the period of one to twelve months preceding admission to the hospital. This loss of weight ranged from 10 pounds in 1 case to 85 pounds in another; in 17 cases the loss varied from 20 to 85 pounds; in 12 cases there was a minimum loss of 40 pounds. In none of the 46 cases was there a significant gain in weight in the twelve months preceding admission to the hospital because of impending gangrene. The average loss of weight in the 22 patients was 62.1 pounds. This positive occurrence in almost half of the cases suggests the possibility of an effect on the peripheral vascular bed and on the peripheral tissues produced by a rapidly changing metabolism. In this limited presentation this phase of the alteration of the metabolism cannot be discussed adequately.

Knowledge and Control of Diabetes

Of the 46 cases: 9, or 19.5 per cent, had no knowledge that they had diabetes; 37, or 80.4 per cent, knew they had diabetes; 19, or 41.3 per cent, had uncontrolled diabetes on admission to the Surgical Service; 27, or 58.6 per cent, had controlled diabetes on admission to the Surgical Service; and 23, or 50 per cent, had been treated in the Diabetic Clinic of the New York Hospital.

This last figure gives a new basis for the calculation of the frequency of gangrene in the patient with diabetes. These 23 patients were under treatment in the Diabetic Clinic of the New York Hospital during a period of time in which a total of 1,791 patients were treated in that clinic. This represents the occurrence of gangrene at the rate of 1.3 per cent. While it is probable that a few other outpatients in this group may have developed gangrene or serious infection of the leg for which they were treated in another institution, the value probably is a more accurate one than that listed above at 2.5 per cent.

Of the 37 cases in which the patient knew of his disease, 11 had been treated by diet alone, 14 by diet and insulin, and 5 by diet and protamine zinc insulin, while 7 had neglected to adhere to a prescribed regimen of diet and

insulin. Therefore, it is seen that 16, or 34.8 per cent, of the patients (9 who had no knowledge of their disease plus 7 who neglected to adhere to a prescribed regimen) developed gangrene while the underlying metabolic disease was in a state of neglect. The fact that 23 patients, half of the entire group, developed gangrene at a time when their diabetic state had adequate supervision and control indicates that regulation of the diabetes is not sufficient to prevent the development of serious infection and gangrene. Obviously, preventive peripheral vascular care is necessary. This will be referred to later. It is a commentary on the state of the public health that 19.5 per cent of the patients in this group of cases are unaware of their diabetes until the development of local conditions leading to gangrene and that 80.4 per cent develop this serious condition despite the knowledge of the disease.

The duration of known diabetes in 37 patients averaged 8.1 years. The longest known duration of diabetes was 35 years. This was in the case of a 68-year-old man whose history revealed that 3 siblings had died of diabetes or of its complications.

General Condition of the Patient

At the time of admission to the hospital 8, or 17.3 per cent, of these patients were febrile and acutely ill. Thirty-three, or 71.7 per cent, were considered to be in poor condition because of generalized arteriosclerosis and accompanying cardiovascular-renal disease. Four, or 8 per cent, were in fairly good condition. Their diagnoses on admission are as follows:

	Case
Good general condition	4
Good general condition and latent syphilis	1
Fever and leukocytosis	1
Fever, leukocytosis, and acidosis	1
Fever, leukocytosis, acidosis, and disorientation	1
Fever, leukocytosis, and pulmonary congestion	1
Fever, leukocytosis, and arteriosclerotic heart disease with hypertrophy	1
Fever, leukocytosis, arteriosclerosis, and cataracts	1
Fever, leukocytosis, arteriosclerosis, and actinomycosis	1
Fever, leukocytosis, arteriosclerosis, and perirectal abscess	1 8
Generalized arteriosclerosis	12
Generalized arteriosclerosis and prostatic hypertrophy	1

In 39 of the 46 cases there was glycosuria varying from 1 plus to 4 plus. Blood chemistry studies showed that all of the 46 had hyperglycemia at the time of admission to the hospital. Nine of 25 cases in which the carbon dioxide combining power of the blood was determined showed a value below normal. In 2 of 29 cases in which the urea of the blood was determined there was retention of urea.

Local Condition of the Foot

The condition of the affected foot at the time of admission to the hospital with regard to the type of pathologic change and its extent is shown in Table 1. It is seen that of the digits the great toe was most frequently the site of early gangrene. Gangrene in association with ulcer or sinus and advancing cellulitis was observed at the time of admission to the hospital in 18 cases—39.1 per cent of the entire group. In only 4 cases was the condition purely infectious with no evidence of gangrene at the time of admission to the hospital.

Etiology of the Local Condition

In 27 of the 46 cases a definite local trauma preceded the development of gangrene and infection. In 7 patients poorly fitted shoes were responsible; in 11 there was undue trauma to the soft parts in the cutting of corns or calluses by the patient himself. The individual injuries are listed in Table 2.

It is at once apparent that the most important phase of preventive peripheral vascular care is in the type of chiropody which the patient receives. Since in this group of cases 33 of the 46 cases manifested advanced generalized arteriosclerosis, it is probable that all of these had some impairment of peripheral sensation and of vision and prob-

ably had some ataxia. Conditions such as these render older people incapable of properly taking care of their own feet. Even in the absence of peripheral vascular symptoms it is my opinion that these diabetic patients should be given the advantage of skilled podiatry and advice as to the choice and fit of shoes. In the New York Hospital Outpatient Dispensary this care is given by the assistant resident surgeon in attendance at the Surgical Clinic. The relation of infection to gangrene in the diabetic subject who also has arteriosclerosis has never been completely clarified. Since 42 of the 46 patients in this series had gangrene of tissue when admitted to the hospital and since 27 of the 46 gave the history of an antecedent trauma that acted as an introitus for infection, it is reasonable to conclude that infection brings on gangrene in at least one-half of the cases. When first seen, it is often difficult to classify the pedal lesion in the diabetic patient as purely vascular or purely infectious in origin. I know of no better clinical classification than that offered by Williams and O'Kane.¹ From their recent publication the classification is herewith reproduced:

CLASSIFICATION OF THE LESIONS OF THE LOWER EXTREMITIES ASSOCIATED WITH DIABETES

Vascular ("3 plus vascular")	{	Marked arterial insufficiency
		Initial gangrene
		No infection
Mixed	{	Marked arterial insufficiency
		Initial gangrene
		Infection superimposed
	{	Moderate arterial insufficiency
		Initial infection
		Gangrene superimposed
Infectious ("4 plus infectious")	{	Slight arterial insufficiency
		Initial infection
		No gangrene
		No arterial insufficiency

Bacteriology of the Local Lesion

In 18 cases cultures were taken from the local lesion. Staphylococcus acting with or without another organism was the causative agent in 12 cases. Various strains of streptococci alone or with another organism were cultured from the affected area in 7 cases. Postoperatively, 3 patients developed gas gangrene, yet the gas bacillus was not cultured from the pedal lesions in these cases.

The bacteriologic reports are as follows:

	Cases
<i>Staphylococcus aureus hemolyticus</i>	5
<i>Staphylococcus aureus hemolyticus</i> and <i>Bacillus coli communis</i>	2
<i>Staphylococcus aureus</i> and nonhemolytic <i>Streptococcus albus</i>	1
<i>Staphylococcus aureus</i> and nonhemolytic <i>Streptococcus beta</i>	2
<i>Staphylococcus albus</i>	1
<i>Staphylococcus albus</i> and nonhemolytic <i>streptococcus</i>	1
<i>Beta-hemolytic streptococcus</i>	2
<i>Bacillus coli</i> and nonhemolytic strepto- coccus	1
<i>Bacillus proteus</i> and nonhemolytic strep- tococcus	1
<i>Bacillus proteus</i>	1
<i>Bacillus coli</i>	1
Total	18

Examination of the Peripheral Vascular Bed

In 25, or 54.3 per cent, of 46 cases the dorsalis pedis pulse was not palpable on the affected side.

In 31, or 67.6 per cent, of 46 cases the posterior tibial pulse was not palpable on the affected side.

In 9, or 19.5 per cent, of 46 cases the popliteal pulse was not palpable on the affected side.

Of 17 cases in which oscillometric readings were recorded, all, or 100 per cent, had markedly diminished or absent oscillometric readings.

Of 18 cases in which accurate surface temperature readings were recorded, the values were equal on the two sides in 1, were 2 to 6 degrees Centigrade lower on the affected side in 15, and were markedly elevated due to regional infection on the affected side in 2 cases.

X-rays of the affected extremity were taken in 35 cases. Fifteen of these showed osteomyelitis of the phalanges or metacarpals. De-calcification of bones was reported in 5 cases. All 35 showed calcification of the peripheral vessels in the affected extremity.

Physical Therapy and Preoperative Treatment

Preoperative physical therapy in the Peripheral Vascular Clinic included the following when indicated: Buerger-Allen exercises, passive vascular exercises,² alternating hot and cold foot baths, competent care of the nails by a physician in the dispensary, attention to

TABLE 3.—FORTY-SIX CASES OF GANGRENE OF THE LOWER EXTREMITY TREATED BY AMPUTATION (64 OPERATIONS)

Cases	Operations
10 cases	Single or multiple amputations of the toe (wound packed open) were done successfully, no reamputation being necessary
5 cases	Amputations of the toe were followed by lower thigh amputation
4 cases (8 operations)	Two successive amputations of the toe were followed by lower thigh amputation
4 cases	Secondary toe amputations were done, no higher amputation necessary
31 cases	Lower thigh amputations were done, 10 of these having been preceded by amputations of the toe or through the foot (1 case)
5 cases	Amputations through the tibia and fibula were successful
1 case	Amputation through the foot was followed by lower thigh amputation

the proper fitting of shoes, lanolin or cottonseed oil inunction to the feet, massage of the feet, high vitamin and high calcium diet, and intravenous sodium citrate solution.³ Patients were instructed to avoid trauma to the feet and to discontinue the use of tobacco. In this branch of the dispensary written instruction sheets are given to the patient. Of the 46 cases reported, only 3 had the advantage of complete preventive therapy in the Peripheral Vascular Clinic. This is explained by the facts that only 23 of the 46 cases of gangrene were under observation in the Diabetic Clinic and that of these 23 only 3 had any complaints with reference to their feet or legs prior to the onset of the local condition for which they were admitted to the hospital. Data are not available at the present time as to the total number of diabetic patients who were treated in the Peripheral Vascular Clinic during the seven and one-half years in which the 3 patients so treated were admitted to the hospital because of impending gangrene.

After admission to the hospital because of infection, gangrene, or impending gangrene, the preoperative therapy was outlined to meet the conditions in the individual case. Hot saline dressings were used in those cases that showed active moist infection superimposed on gangrene; Dakin's dressings were used for open ulceration; zinc peroxide packs were used for sinuses; a cradle with a thermostatically regulated incandescent bulb (Valstat Vasculator*) was used in cases of dry gangrene; and alternate suction and pressure and Sanders' oscillating bed⁴ were used in those cases in which the peripheral circulation seemed to be benefited and the infection was not activated by these mechanical aids. In 26 of 46 cases the heat cradle was persistently used in the preoperative period. Transfusion

* Supplied by Valverde Laboratories, New York City.

FIG. 1. Level of amputations in 64 operations on 46 patients.

of blood, intravenous saline, intravenous sodium citrate solution, and sulfanilamide were used as indicated in the particular patient in preparation for operation. All patients were treated for dehydration before operation.

Operative Treatment

Forty-six cases of gangrene of the lower extremity in diabetic subjects were treated by amputation as shown in Table 3. At the time of admission to the hospital there were only 4 cases in which the infectious process had not yet developed into gangrene. These 4, however, developed gangrene subsequently so that, making use of the classification referred to above, all 46 fall into the groups of purely vascular or of mixed vascular disturbance and infection. Simple incisions for drainage in this series of cases did not prevent the extension of gangrene. Here, the clinical peculiarities of infection in the extremity of the diabetic patient are strikingly brought out. Infection of the toe, whether staphylococci, streptococci, or of mixed organisms, demonstrates an especial tendency toward the development of regional thromboses with resultant gangrene. Wounds heal slowly. Tissues are nonresistant to infection. Areas of gangrene thus produced are characterized by massive subcutaneous sloughs of tissue with relatively little purulent exudation. Accumulation of pus, when formed, readily dissects along fascial planes to invade new tissue spaces higher in the extremity, gravity

undoubtedly being a factor. Because of this, the patient with an infection of the toes or foot is kept prone in bed with a small pillow under the ankle so that purulent material may drain out of the sinuses rather than be carried, by its own weight, cephalad through the adjacent tissue spaces of the foot and ankle. Grodinsky⁵ has demonstrated by dissection and injection methods eleven fascial spaces in the foot and leg. Reid⁶ has emphasized the importance of position in the management of infection of the foot in association with peripheral vascular disease. These observations, repeatedly emphasized by all clinicians, constitute the evidence that there is at work in the diabetic patient a factor that is not controlled by therapy with diet and insulin, a factor that militates against the patient's recovery and increases the hazard of operation. This situation demands especial attention in treating the surgical diabetic patient. In a few clinics this problem has been met by the establishment of a so-called "diabetic team" consisting of surgeons and physicians who, together, visit the surgical diabetic patients in the hospital daily. In the institution from which I am reporting no such team has been in operation, though the resident surgeons have called frequently and unhesitatingly on the interested members of the surgical and medical attending staffs in an effort to give to this group of patients their best chance of survival with physical efficiency. The major problems concern the level of amputation; the type of operation; whether to leave the wound open, to close it, to close it loosely, or to drain it; and the selection of type of anesthesia. I do not believe that it is possible to be dogmatic regarding the level of amputation. This must be determined after consideration of the extent of the gangrene and infection, the state of the patient, the ability of the patient to accept a prosthesis subsequently, and, most important, the state of the circulation in the extremity. There are, in my opinion, no completely satisfactory tests of the circulatory efficiency of the extremity by which the ideal level for amputation can be determined. The saline wheel test (Stern⁷), the histamine test (De Takats⁸), peripheral nerve block (Morton and Scott⁹), the tourniquet test (Brooks¹⁰), and arteriography have not been found to be wholly reliable guides. Arteriography is not performed without danger of injury to the peripheral arterial bed. The presence of persistent pain productive of fatigue and the presence of fever or of extending gangrene and infection do, however, indicate the neces-

FIG. 2. Area involved in gangrene in 31 cases which came to lower thigh amputation.

sity for amputation, and there are certain general rules that may guide the surgeon. Simple amputation of the toe probably will be successful if there has been little pain, if the infection has not spread over the dorsum of the foot, and if the dorsalis pedis pulse is palpable. In this series this procedure was successful in 10 cases; no higher reamputations were necessary. In 9 cases, amputations of the toe had to be followed by lower thigh amputations and, in 1 case in which amputation was done through the foot, failure to accomplish wound healing followed and lower thigh amputation was necessary. Table 3 lists these data. The final disposition in the 46 patients in this series was 31 with lower thigh amputations, 5 with amputations through the tibia, and 10 with simple amputations of the toe. This is shown in Fig. 1. Secondary amputation has been frowned on rightfully, since this procedure is known to carry with it an increased probability of loss of life.

Fig. 2 is of value in an attempt to determine which part of the foot is most likely to be the starting point of spreading gangrene. It gives the primary site of gangrene at the time of admission to the hospital on the 31 patients

who finally had a lower thigh amputation. It is my impression that because of the proximity of the great toe to the tendon sheath of the extensor hallucis longus tendon gangrene of this toe is of more serious consequence than gangrene of any of the other 4 toes. Anatomically, infection travels a shorter distance from the great toe to reach the ascending tendon sheaths of the dorsum and sole of the foot than does infection from the other 4 toes. As noted by Grodinsky,⁵ the infection in each of the 4 other toes may spread to the adjacent tissue space, but it is unlikely that the infection travels as rapidly in these spaces as it does through the tendon sheaths leading from the great toe.

Technic of Amputation

In the performance of simple amputation of the toe, the digit was amputated through the proximal one-third of the proximal phalanx, the flexor and extensor tendons were sutured to each other over the bony stump, and the wound was packed open. This was the operation done on 10 patients. Because of the extent of the gangrene it was necessary in operations on 17 patients to disarticulate the toe at the metacarpophalangeal joint,

TABLE 4.—COMPLICATIONS IN 12 OF 31 CASES FOLLOWING LOWER THIGH AMPUTATION

Age of Patient	Previous Amputation	Operative Treatment of Stump	Complication	Result	
58	None	Closed with drains	Bronchopneumonia	Died	} Death due to cardiorespiratory complication
58	None	Wound left open	Bronchopneumonia	Died	
68	Toe amputation	Wound loosely closed	Cardiac failure Hydrothorax	Died	
67	None	Closed with drains	Cardiac failure	Died	
67	None	Closed with drains	Cardiac failure	Died	} Recovered
63	None	Closed. No drains	Pulmonary embolism	Recovered	
72	None	Closed. No drains	Postoperation psychosis	Recovered	
57	None	Closed with drains	Gas gangrene of stump	Recovered	
49	2 toe amputations	Wound left open; secondary closure	Abscess of stump	Died	} Death due to complications of the amputation stump
60	None	Wound loosely closed	Gas gangrene of stump	Died	
63	Toe amputation	Closed. No drains	Gas gangrene of stump	Died	
76	None	Wound left open	Secondary hemorrhage from stump Pulmonary edema	Died	

after which the head of the metatarsal was removed with a rongeur, the tendons were secured, and the wound was packed open. Similar technic, amputating through the proximal one-third of the metacarpals, was used in 1 case, the wound having been left open. In 4 cases, amputations were done through the upper third of the tibia and fibula, and in 1 case it was done through the middle third of the tibia and fibula. Here the amputation was carried out so that flaps of soft tissue 2 to 3 inches long projected distal to the sectioned tibia. The fibula was divided at a point 1 inch higher than the level of the division of the tibia. These 5 cases were the most favorable of those subjected to major amputation. Four of these wounds were closed without drainage, while in 1 case it was necessary to insert drains.

In 31 cases of lower thigh amputation the procedure involved circular incision at a point in the lower third of the thigh just above the quadriceps bursa. The subcutaneous tissues and skin are retracted, and muscle and fascia are divided at a point 1 or 2 inches above the skin incision. In order to prevent retraction of the muscles and fascia of the posterior aspect of the thigh, the knee is held flexed at right angles while they are being divided. The periosteum of the femur was elevated to a point 1 to 2 inches above the level of the resection of the muscles, and the bone was divided with a Gigli saw at this point. The marrow cavity was not disturbed; bleeding from the bone was controlled with Horsley's bone wax, sharp spicules of cortical bone were removed

by file or with a rongeur. The femoral artery and vein were doubly ligated with silk; plain catgut was used for ligature or transfixion of bleeding points in the muscle or subcutaneous tissues. The sciatic nerve was dissected free from surrounding tissues, exposed for a distance of 2 inches by traction, and then ligated with plain catgut. The nerve was divided distal to the ligature and injected with a 2 cc. of 95 per cent alcohol proximal to the ligature. Closure in these 31 cases was as follows: closed without drains, 13 cases; closed with drains, 2 cases; partially closed, 3 cases; and wound open, 13 cases.

Anesthesia

In the operations for amputation of the toe it was the policy to use local anesthesia. For major amputations, spinal anesthesia was selected whenever this anesthetic was not contraindicated because of severe hypertension or myocardial damage. Spinal neocaine (120 to 150 mg.), given into the third lumbar interspace without barbotage, serves admirably to anesthetize the entire thigh and was used successfully in 60 per cent of the major amputations in this series. Because of cardiovascular impairment, cyclopropane or ethylene was used in the other 40 per cent of the patients.

Complications

Serious postoperative complications occurred only in the major amputations. In the 31 amputations through the lower thigh there were 12 complications, an incidence of

TABLE 5—MORTALITY (46 CASES, 19.56 PER CENT)

Type Amputation	No. Amputations	No. Deaths	Percentage	Followed by Resamputation
Lower thigh	31	9	29.03	0
Through tibia and fibula	5	0	0	0
Through foot	1	0	0	1
Toe amputation	27	0	0	9

38.7 per cent. In the 5 amputations through the tibia and fibula there was only 1 complication, an incidence of 20 per cent. An analysis of these complications with regard to the age of the patient and the final outcome of the case is of interest. Table 4 shows that 7 patients had complications of the cardio-respiratory system, of which 5 died and 2 recovered. Five were complications of the amputation stump. In 2 cases the complication in the stump undoubtedly was accounted for by the unhealthy granulating wounds of the foot following unsuccessful amputation of the toe. In the 3 patients who developed gas gangrene of the stump, the portal of entry for the anaerobic infection was in the foot. One of these had a draining sinus at the metacarpophalangeal joint, 1 had 3 gangrenous toes with adjacent infection, and 1 had an unhealthy granulating ulcer following amputation of the toe. The patient who died following hemorrhage from the stump was a debilitated 76-year-old man whose wound had not healed but who, fourteen weeks after operation, had been allowed up in a chair in an attempt to avoid the complication of hypostatic pneumonia. The average age of the 13 patients who developed serious postoperative complications was 62.5 years—a little higher than the average age of 62.1 for the entire group.

Mortality

Thirty-six major amputations were done with 9 deaths in the hospital, a mortality rate of 25 per cent. All 9 deaths occurred in the 31 lower thigh amputations, a mortality rate of 29.03 per cent. Five amputations through the tibia, 1 amputation through the foot, and 27 amputations of the toe were done without complications and without deaths. The case mortality (9 deaths in 46 cases of diabetic gangrene) was 19.56 per cent (Table 5).*

Lower thigh amputation for arteriosclerotic gangrene in the diabetic patient carries a higher mortality rate than does the same operation for arteriosclerotic gangrene in the

patients without diabetes. In the same period of time that the above-listed 31 diabetic patients underwent lower thigh amputation, 26 patients with arteriosclerotic gangrene were treated by the same operation. The mortality in the diabetic group has already been listed at 29.03 per cent; in the arteriosclerotic patients without diabetes the mortality rate was 15.3 per cent (4 deaths).

Prostheses

Of the 31 cases in which lower thigh amputations were done: 9 died; 9 were fitted with, and satisfactorily wore, an artificial leg; 1 had both legs amputated and was unable to wear a prosthesis; 7 preferred not to wear a prosthesis; 1 was unable to wear a prosthesis because of senility; 2 were not followed, and in 2 there was not a sufficient lapse of time to permit fitting of a prosthesis. Excluding the 9 deaths, the 2 patients who were not followed, and the 2 who are not yet fitted with a prosthesis, there are 18 patients of whom 9 or 50 per cent are wearing an artificial leg with comfort and satisfaction.

Of 5 cases in which amputation was done through the tibia and fibula: 3 wore a prosthesis satisfactorily, 1 was unable to wear a prosthesis because of senility, and in 1 there was not a sufficient lapse of time to permit fitting of a prosthesis. Excluding the last case in which there has not been sufficient lapse of time, there are 4 patients in this group of whom 75 per cent are wearing a prosthesis satisfactorily.

Consideration of these follow-up reports brings one to the rather startling realization that out of the 37 patients still surviving only 12 or approximately one-third are able to pursue their vocations as well as before the illness. Or, compared to the entire group of 46 patients, only 12 or about one-fourth are engaged in normal daily activity. This realization serves to emphasize the economic importance of the development of gangrene and infection in the diabetic subject. However, the failure to rehabilitate a greater percentage of this group becomes less discouraging when it is realized that the majority of patients were 62 or more years of age and that the average diabetic patient dies at 64.9 years of age. Of

*Six additional cases were treated by amputation between March 1, 1940, and January 1, 1942. Four of these recovered following amputation of 1 toe, while in 2 cases amputation was done below the knee. The addition of these 6 cases to the 46 listed above lowers the case mortality to 17.3 per cent.

vast importance to the patient and the community is the prolonged period of hospitalization in this disease. The average time in the hospital for this group of patients was seventy and three-tenths days.

It is generally recognized that the span of life in this country is being extended, and statistics of the Department of Health of New York City¹¹ indicate that in diabetes the average age at death has steadily risen from 59.5 years in 1919 to 64.9 years in 1939. In this presentation it was pointed out earlier that 1 in 40 diabetic patients probably will develop infection or gangrene of the lower extremity. Again quoting the Bulletin of the Department of Health¹¹ facts have been presented which indicate that in New York City the total number of diabetic patients is somewhere between 50,000 and 75,000. Projecting this estimate, one finds that somewhere between 1,250 and 1,875 diabetics now walking the streets of New York City are potential cases of gangrene or infection of the lower extremity. The public health aspect of this complication is emphasized when one continues the projection to find that seventy hospital days are needed for each of these. The management of infection and gangrene in diabetes mellitus presents itself as a major problem of the community. The hope for lessened morbidity and decreased mortality resulting from peripheral vascular complications in the diabetic patient lies in the drive to perfect the therapy of the peripheral vascular disease in the care of these patients.

Discussion of Symposium

Dr. Frederick W. Williams, *New York City*—It is interesting to have the statistics from four private hospitals summarized. I was impressed with the cost of these comparatively few cases in private hospitals, but you will see that the city is doing its share, for at Morrisania, which is a 500-bed hospital, 452 lower extremity lesions have been admitted. And a hospital such as

Kings County in Brooklyn probably has even more admissions. Of the 452 cases, 411 were treated and 41 A. O. R., 254 were treated non-operatively, and 157 were operated on, 105 having calf or thigh amputations. Fifty-two had I & D or toe amputations. The key to success is close cooperation between the medical management and the surgical management. Statistics were presented four years ago from Morrisania, and two years ago from the four divisions of Bellevue. And we know that the reduction that has taken place at Morrisania is due to close cooperation, for the medical management is fairly well established.

I do not think that the outlook depends on a single pre- or postoperative blood sugar.

When we come to the surgical aspect, we heard four papers presenting a lot of statistics and after all had been presented, confusion resulted. I know I am confused. We are talking in terms of diabetic gangrene which is the wrong term to use as it is all-inclusive and was used when nothing was known about peripheral vascular disease. In addition to the vague statement of "diabetic gangrene," varied opinions of indications for operation, opinions of dressings, and kind of chemicals used, etc., were presented. With these many variations we then have studies in mortality statistics. Often the series are small. In this confusion, we are confronted with comparative studies of mortality.

Before we go any further, we should analyze our logic and see what we are comparing and what the lesions are, for they are not all the same. At Morrisania for five years, the lesions have been classified according to basic pathology, vascular impairment, and infection. With two elements, there must logically be three classes: (1) purely vascular; (2) purely infectious; (3) mixed—arbitrarily according to degree of vascular impairment together with infection. This is determined by complete physical examination for peripheral vascular disease. Palpitation of vessels, heat, and pain were mentioned here, but nothing was said about nourishment of the nails, hair, history of cramps, general status of arteries and veins, and all other signs of peripheral vascular disease. (Instrumental observations are not essential.)

To explain the above classification: (1) vascular, i.e., senile gangrene; (2) infectious, i.e., osteomyelitis; (3) mixed—both—3 plus—marked signs of peripheral vascular disease, initial gangrene, infection superimposed, 2 plus—moderate signs of peripheral vascular disease, initial infection, gangrene superimposed, 1 plus—slight signs of peripheral vascular disease, initial infection, no gangrene.

We talk about lesions in our hospital according to this classification. In this way we know we are talking about the same thing; from this we begin to talk about indications for operation and what should be done. The urgency of the operation and the level of operation depends on

the severity of the infection and the degree of vascular impairment or combinations.

Classification	Character of Lesion	Surgical Procedures
1. Vascular	Superficial Localized Extensive	No operation Amputation at calf if collateral circulation is good at knee; thigh if not
2. Infectious	Superficial Localized Spreading	No operation I & D I & D
3. Mixed	3 plus Spreading	Amputation at thigh (urgent)
	2 plus Spreading	Amputation at calf (urgent)
	1 plus Superficial Localized Spreading	No operation I & D; toe amputation Amputation at calf (urgent)

It isn't fair to compare mortality. At our hospital we may do a toe operation, and someone else may do a thigh operation on the same type of lesion. In the old days the surgeon stood at the foot of the bed, saw a gray-haired patient with diabetes and a sore foot, called it diabetic gangrene, and said: "Advise a midthigh amputation immediately." His logic was that in the light of his experience the only ones that got better were those done high and early. His logic is sound in deduction but his major premise is faulty, for in the light of his experience a knowledge of peripheral vascular disease was not included. He saw badly infected feet with good circulation and he did a thigh amputation with a good result, but he threw away a lot of good knees. On the other hand, he saw vascular legs with just a toe gangrene and tried to do a toe amputation in a field where the circulation did not permit of the trauma of such surgery, and he got recurrent gangrene. This was faulty due to his lack of knowledge of peripheral vascular disease.

It is important to make studies of comparative mortality, but I believe that they would be of more value if the New York Diabetes Association would first set up some criteria for the classification of lesions—similar to what the Heart Association had done.

It is faulty reasoning for us to compare mortality percentages of operative procedures when these operative procedures are not done on similar clinical lesions. Surgeons do not compare death rates from gastroenterostomy, for some men do them for appendicitis and others do them for gallbladder disease. Comparative mortality figures can only be of value for the same lesion. Our logic is faulty if our conclusions are based on comparative studies of middle terms without the major premise being identical. Years ago doctors treated all mitral stenotic murmurs or auricle fibrillations and "dropsy" as heart disease

with digitalis. By establishing definite criteria, the Heart Association has done a tremendous job in clarifying that phase of medicine. I regard it as an opportunity for the Diabetes Association to do the same to help doctors out of this confused state of mind by establishing definite clinical entities with specific criteria.

Dr. Henry H. Faxon, Boston—The first thing I should like to do is to heartily endorse the plan for classification presented by Dr. Williams. Further, by way of introduction, I should like to point out that it is erroneous to believe that only the specialist can determine who has impaired circulation. All of us, without any complicated equipment, can evaluate clinically and effectively these conditions.

Since the Circulatory Clinic began functioning at the Massachusetts General Hospital in 1928, there have been 250 diabetic patients admitted to the house because of peripheral circulatory disorders. Of the 250 cases, 50 per cent have come to major amputation, and our mortality in this operative group has been 15.7 per cent. The actual carrying out of a surgical procedure in this group of patients is less important than the decision as to what is to be done. Our resident surgeons frequently do the major amputations but are never allowed to decide when and at what level these are to be carried out. A minor operation in this group of patients is always done by one of the visiting surgeons, since it potentially is a greater risk in many ways than a major procedure. A minor amputation in this group will frequently be a major calamity if it is ill-advised.

At the Massachusetts General Hospital we feel that in the diabetic group where infection is marked and the circulation poor the simplest operation should be done, and we think only of ridding the patient of his infection and not in terms of prosthesis. Fifty per cent of the diabetic patients that have been admitted to the Hospital for circulatory disorders have come to major amputation; 10 per cent of the type with advanced infection have had a preliminary simple guillotine amputation through the lower leg, left wide open, followed by a secondary closed amputation at a higher level at a later date. We feel that drains are unwarranted.

Essentially all of these patients are poor risks, and it is significant to find that of our successfully amputated cases one-third had died within two years, and two-thirds within a five-year period. We personally feel that a lower leg amputation in a person with good circulation is desirable but is only rarely applicable to the diabetic arteriosclerotic patient.

INVOLUTIONAL MELANCHOLIA

EDWARD A. STRECKER, M.D., Philadelphia

NATIONS and human beings, alike, have epochs in their existence during which they are exposed to serious hazards, incidental and epochal, in their life histories. Like the individual, the nation is conceived and born. If it survives the helplessness and insecurity of its infancy and adolescence, it comes to a lusty and powerful maturity. At this stage of its existence it meets risks and threats, both external and internal, with confidence and strength. This period may be long in duration but sooner or later the nation reaches its climacteric. At its climax it is at the very height of its power and is able to harvest the fruits of its experiences, economic and cultural. But the handwriting is on the wall. Its zenith is at the same time the beginning of its nadir. Although it may be postponed and, sometimes, almost indefinitely deferred, yet regression has begun. Its next and final epoch, the epoch of its decline and fall, is inescapable, for, like human beings, nations are not only conceived and born but also they must die.

The hazards of any nation are economic, political, social, moral, and spiritual. During certain spans of its existence the nation is more vulnerable to one or more of these threats than at other times.

The epochal life hazards of human beings are physical and mental. Often they are serious enough to threaten continued existence, bodily or mental; always they are significant enough to imperil future satisfactory physical and mental adjustments.

For instance, the pediatrician will tell you of the physical risks in infancy. He will make clear to you that even in this day of scientific advance the mortality among babies is still high. In that day when their physical insecurity was not buttressed by the efforts of science, their ranks were literally decimated by numerous diseases.

Another example of epochal vulnerability to physical threats may be found at the opposite end of the pole of life—old age. Here, again, even the keenest lances of science cannot hold back indefinitely those physical deteriorations that come with old age.

Given by invitation at the Thirty-fifth Annual Meeting of the Sixth District Branch of the Medical Society of the State of New York, Mary Imogene Bassett Hospital, Cooperstown, New York, September 18, 1941.

Professor of psychiatry, University of Pennsylvania, School of Medicine.

Chronology entails not only physical hazards but also serious mental hazards. For instance, in the postadolescent period the chronologic hazard of schizophrenia is significantly shown in the statistical peak reached by this psychosis. Strikingly, in the second decade there occurs the massive schizophrenic retreat from the joys and sorrows, from the promises and the threats of mature emotional life and its competitive heterosexual and heterosexual contacts and demands.

The Climacteric

Obviously, there are particular dangers and risks peculiar to the epoch of the climax and obviously, too, they are either preponderantly somatic or preponderantly psychic.

The flexibility and endurance of young tissues no longer exist, and the pelvis, the heart and circulatory apparatus, and the metabolic chemistry all become increasingly vulnerable.

The armor of the psyche begins to wear a bit thin. If there is a considerable flaw in the resistance of the personality, it may mean a dangerous exposure. There is the encroachment of the many liabilities, intrinsic and extrinsic, of the climacteric. The period of regression has begun. Life cannot be lived over. Gone forever is the resiliency of youth. The mistakes of the past must stand. It is not at all remarkable that a usual accompaniment of the menopause is a certain amount of anxiety, apprehension, and indecision.

Definitely imperiled is the rigid, meticulous, slave-to-detail personality, the combination of perfectionist and New England conscience. There is scarcely enough resistive strength to turn away the increasing number of outer and inner thrusts. No longer can the integrity of the total personality stand up under the lash of an overdeveloped and unrelenting superego. Too often, such individuals are through with fighting and accept the *coup de grace* of a psychosis.

All in all, the climacteric, not only for women but also for men, is an epoch of insecurity. It carries with it a triple threat: somatic, notably cardiovascular, pelvic, chemicoendocrinal-metabolic; environmental, such as the increasing likelihood of failure to attain success in life, financial reverses, disappointments, family worries, the increasing toll of relatives and friends taken by death, etc.;

the inner psychic turmoil and perhaps disaster wrought in a vulnerable personality.

Etiology

The addition of a few facts, largely statistical, more or less complete our etiologic information.

The sex ratio is about 3 women to 1 man.

The age range in women is from about 40 (or even earlier if there has been an artificial menopause) to about 55; in men, roughly from 50 to 65.

Often it seems that the "step" from climacteric to psychosis is a relatively short one. In other words, even within the so-called "normal" range, it is not unusual to find patterns of jealousy, rapidly shifting emotional states, mild depressive reactions, impulsivities of conduct, marked irritability, hypochondriacal sensations.

It seems to me that before completing an utterly drab picture, I should paint in a few bright lights. In one sense it is true that the climacteric is the beginning of the end, but it is a "long last" and, likewise, it is true that only in its accomplishment and, perhaps, for a subsequent decade, is a peak attained. It is the peak of intellectual, emotional, and experience maturing. Often, in the Europe of the past, intelligent women in this age epoch directed and, indeed, sometimes dominated to an amazing degree the political and cultural movements of the day. This has been far less true in the United States, where advertising propaganda has erected a pedestal and placed upon it a "boyish, slenderized form of flaming feminine youth" whose development from the neck up will require many years before it is consummated. Somewhat feebly, perhaps, I have tilted this lance of argument and promise with the "old wives tales" to their daughters—that at the menopause they are apt to "go insane," that at this time their husbands will lose interest in them and seek the company of younger and more attractive women and, in short, that it is a direful and calamitous period of life.

Symptomatology

Do the involutional psychoses, particularly involutional melancholia, belong to the manic-depressive group? Fairly soon I may be in deep clinical water but, if I could restrict myself to the following simple explanation, no great difficulties would be encountered.

1. A psychosis occurring during the "time" of the climacteric—"time" being flexibly in-

terpreted from the standpoints both of the age and the duration of the process.

2. There not having been any previous manic-depressive episodes.

3. A clinical pattern in which motor retardation is replaced by motor overactivity, ranging from restlessness to frenzied agitation.

The depression is just as deep or even deeper, as is witnessed in the depressive phase of manic-depressive; the self-accusation is often more pronounced and the suicidal trends more dangerous, since there is less apt to be the paralyzing effect of retardation. In a considerable segment of the patients the ideational processes are active with a rich association of ideas, but in even a larger segment there is poverty of thought. Although the patient may be vocally energetic, it is largely repetitive—"Oh, my God! oh, my God!" etc., etc.

The leading symptomatic motifs in an average instance of involutional melancholia may be briefly summarized as follows:

Emotional State.—This is characterized by marked depression, often presenting strong admixtures of apprehension.

Self-blame—self-accusation is usually quite severe—is apt to contain interesting admixtures of the grandiose which has not received sufficient clinical attention. One patient in a state of frenzied self-accusation tells of the punishment she will receive: "I am to be boiled to death in a solid gold kettle!" There is another patient, failing to produce horror and disgust in the psychiatrist, invariably concludes her story of "my vile sexual life" by describing with much histrionic effect "the night when I had sexual relations with forty-three Russians."

Somatic Delusional Formation.—This is frequently a part of the clinical picture and varies from hypochondriasis to the expression of gross somatic delusions: "Everything gone—everything out of me, no stomach, no lungs, no insides, just a shell. All my organs have passed out of my rectum. There is nothing in between. There is nothing left but hands and feet and eyes. This is a miracle—no breath—or anything—Oh, God!—not an earthly thing is left."

Motor State.—Here, as has been indicated, there is a range from mere restlessness to frenzied agitation.

Consciousness and Orientation.—All in all, these cases are amazingly little disturbed and, frequently, a patient will interrupt a delusional outburst in order to observe with clarity and report with accuracy some trivial incident

INVOLUTIONAL MELANCHOLIA

The hazards of any nation are economic, political, social, moral, and spiritual. During certain spans of its existence the nation is more vulnerable to one or more of these threats than at other times.

The epochal life hazards of human beings are physical and mental. Often they are serious enough to threaten continued existence, bodily or mental; always they are significant enough to imperil future satisfactory physical and mental adjustments.

For instance, the pediatrician will tell you of the physical risks in infancy. He will make clear to you that even in this day of scientific advance the mortality among babies is still high. In that day when their physical insecurity was not buttressed by the efforts of science, their ranks were literally decimated by numerous diseases.

Another example of epochal vulnerability to physical threats may be found at the opposite end of the pole of life—old age. Here, again, even the keenest lances of science cannot hold back indefinitely those physical deteriorations that come with old age.

Given by invitation at the Thirty-fifth Annual Meeting of the Sixth District Branch of the Medical Society of the State of New York, Mary Imogene Bassett Hospital, Cooperstown, New York, September 18, 1941.

Professor of psychiatry, University of Pennsylvania, School of Medicine.

Chronology entails not only physical hazards but also serious mental hazards. For instance, in the postadolescent period the chronologic hazard of schizophrenia is significantly shown in the statistical peak reached by this psychosis. Strikingly, in the second decade there occurs the massive schizophrenic retreat from the joys and sorrows, from the promises and the threats of mature emotional life and its competitive heterosexual and heterosexual contacts and demands.

The Climacteric

Obviously, there are particular dangers and risks peculiar to the epoch of the climax and obviously, too, they are either preponderantly somatic or preponderantly psychic.

The flexibility and endurance of young tissues no longer exist, and the pelvis, the heart and circulatory apparatus, and the metabolic chemistry all become increasingly vulnerable.

The armor of the psyche begins to wear a bit thin. If there is a considerable flaw in the resistance of the personality, it may mean a dangerous exposure. There is the encroachment of the many liabilities, intrinsic and extrinsic, of the climacteric. The period of regression has begun. Life cannot be lived over. Gone forever is the resiliency of youth. The mistakes of the past must stand. It is not at all remarkable that a usual accompaniment of the menopause is a certain amount of anxiety, apprehension, and indecision.

Definitely imperiled is the rigid, meticulous, slave-to-detail personality, the combination of perfectionist and New England conscience. There is scarcely enough resistive strength to turn away the increasing number of outer and inner thrusts. No longer can the integrity of the total personality stand up under the lash of an overdeveloped and unrelenting superego. Too often, such individuals are through with fighting and accept the *coup de grace* of a psychosis.

All in all, the climacteric, not only for women but also for men, is an epoch of insecurity. It carries with it a triple threat: somatic, notably cardiovascular, pelvic, chemicoendocrinal-metabolic; environmental, such as the increasing likelihood of failure to attain success in life, financial reverses, disappointments, family worries, the increasing toll of relatives and friends taken by death, etc.;

necessary to requisition the diagnostic and therapeutic skill of the specialist in every field of medicine and surgery.

Occupational Therapy.—Unquestionably, wisely selected and skillfully supervised occupational therapy often makes life bearable for the patient. The nature of the finished product is not important. Important are the facts that energy that would be uselessly and destructively expended is turned into interesting channels; that the work is a hostage to the reality to which it is hoped the patient will be returned; and that gloomy, foreboding, and suicidal thoughts are made less oppressive and sometimes transmuted into faint stirrings of hope which may grow into recovery.

I knew the instance of a talented woman, a sculptress, deep in the throes of a profound melancholia. Retrospectively, she told of being tormented almost constantly by horrible suicidal thoughts, always with the content of finding death by breaking her neck. She was induced to try her sculpturing again. Finally, she completed a beautiful figurine—a female figure, *head thrown back at a right angle to the body*, long hair streaming down the back. The completion of the figurine was the beginning of the end of the melancholia. Soon the patient was well. Later, she confided that the suicidal thinking and planning had passed out of her into the modeling clay.

Nursing Care.—The nurses are with the patient almost constantly. It is of the utmost importance not only that they be skilled in psychiatric nursing technics but also that they have an adequate understanding of the psychopathology of the involutional psychosis. Unless they are equipped in this way, they cannot intelligently combat the attempt of the patient to remain under the cover of unreality, nor can they be effective in assisting the physician in leading the patient back to reality.

Psychotherapy.—In the large majority of instances patients are not accessible to anything but the more simple forms of psychotherapy. However, it is a mistake to underestimate the importance of simple reassuring and suggestion therapy. Many recovered patients testify to the courage they derived from reiterated suggestion and reassurance.

Treatment

The somewhat gloomy prognostic forecast in involutional melancholia has been made brighter during the past decade by energetic researches in three fields: endocrinologic-

chemistry, so-called psychosurgery, and the drastic therapies.

1. Because of its limited area of application, the operation of prefrontal leukotomy is considered first. It was suggested in 1936 by Moniz, a Portuguese surgeon. Originally, he employed alcohol injections into the centrum ovale. Later, he used the technic of cutting, with a leukotome in the prefrontal area bilaterally, three cores, one mm. in diameter, leaving *in situ* the cut tissue.

In selected cases the clinical results appear to be quite good. An important factor in the production of improvement is the cleavage that is produced by the operation between the ideational content of the psychosis and the vivid and dynamic emotional matrix of apprehensive depression in which it is embedded.

With a single exception, I have refrained from advising the operation of prefrontal leukotomy in involutional melancholia, adhering to the following rather rigid criteria: a duration of the psychosis of more than one year, unquestionable chronicity, absence of cardiovascular and other contraindications to brain surgery, failure of all other methods of therapy, and the presence of an exceedingly severe symptomatology with a strongly moving apprehensive-depressive content so that the life of the patient is extremely burdensome and the care of the patient unsatisfactory.

2. Endocrine therapy still gives more promise than fulfillment, but the promise is a valid one. Even though the clinical course is not much influenced, yet, stilbestrol given orally to women is capable of producing estrin saturation, "as evidenced by the changes in urinary A. P. H. and estrin values, by the induced uterine bleeding, and by other clinical signs of estrin effect.

"Testosterone administered by intramuscular injection in male involuntions is capable of producing sexual stimulation, a general improvement in physical well-being and may reduce symptoms arising from benign prostatic hypertrophy. Its beneficial effect in the psychotic stages is questionable but some improvement has been noted in two men with early involutional melancholia.

"Parathormone administered hypodermically in twice daily doses of 50 and 100 units, together with calcium and ammonium chloride, increases serum calcium levels. This therapy has no effect on the clinical course of the disorder."

3. Concerning the third direct treatment

that has occurred within the range of her vision.

If one could stop here it would be well and good, but one cannot. There are innumerable modifications of this clinical picture. Only a few of these modifications may be mentioned: feelings of unreality; nihilistic, delusional conceptions; ideas of poverty; catatonic phenomena; many emotional shadings including pessimism, irritability, sarcasm, irony; sadistical attitudes; hallucinosis; and, finally, paranoid trends often well developed and systematically presented and with a considerable sexual content.

These modifications and sometimes distortions of the original pattern have led to the inclusion of a vast amount of allied and alien clinical material. Thus, there have been included at the earlier age-end of the scale many late schizophrenic reactions and at the later age-end, arteriosclerotic reaction types.

This is not laudable psychiatry. Naming things too soon before sufficient information has been acquired blocks the accumulation of knowledge. Hair-splitting discriminations, with the addition of high-sounding nomenclature, have not really opened up the unexplored areas of the territory of the involutional psychoses.

The so-called *reactive depressions* constitute a significant exception. Since they probably do not carry with them the constitutional implications of manic-depressive, it is important that they be clearly distinguished. They are marked chiefly by the fact that they are severe emotional reactions to real and disruptive life situations, and the connecting thread between the "cause"—i.e., the life situation—and the "effect"—i.e., the depression—remains unbroken in the mind of the patient for a long time and, not infrequently, it is never lost.

Course and Prognosis

Involutional melancholia tends to be a lengthy psychosis. A duration of a year or more is not uncommon. The recovery rate is about 23 to 40 per cent. About 25 to 32 per cent become chronic, and about 1 of every 5 die by suicide and intercurrent disease.

Unfavorable prognostic indications are: a duration of more than one year, an age of more than 55 years, the intensification of symptoms referable to arteriosclerosis of the cerebral vessels, marked insufficiency of affect, peevishness or autoerotic behavior, and continued gross somatic delusions.

Treatment

Preventive treatment has not been sufficiently stressed. At the approach of the climacteric, every woman is entitled to a cardiovascular and pelvic examination and an endocrine survey; every man should have a thorough examination. Advances and researches, important and sometimes brilliant, in the field of endocrine chemistry make excellent prophylactic promise for the future.

In the area of protective psychologic therapy there is an opportunity for pioneer mental hygiene. To sweep away the clutter of ignorance, superstition, and sexual folklore, which has accumulated around the truth of the climacteric, in itself would be a noteworthy achievement. The physician can be constructively helpful without trespassing beyond the limitations of honesty. I doubt if an attitude of expansive optimism and Pollyannaish preachments along the lines of "business as usual" during the climacteric is truly helpful. True enough, it is a natural epoch, but so is the childbearing period natural and physiologic, yet some women do lose their lives in childbirth. Actually, the complexities of modern civilization have introduced complicating factors, personal and social, so that the terms "natural" and "physiologic" must be used with considerable reservation in considering the climacteric and in attempts to protect human beings from its hazards.

Hospital and Sanatorium Treatment

Not only because of the considerable suicidal risk but also because of the constant need of treatment facilities of the greatest variety, it is usually imperative for the patient to spend some time in a mental hospital or sanatorium.

Hypnotic Medication—It is doubtful whether one can hope to escape the employment of hypnotic medication throughout the course of an involutional melancholia. The problem is one of avoidance of overdosage, the strict limitation of narcotic and seriously habit-forming drugs, and the minimization of the use of hypnotic drug therapy by the employment of the continuous bath and other hydrotherapeutic measures.

Diet.—A full and vitamin-rich diet is indicated.

Internal Medicine.—Each patient is a problem in internal medicine and, sometimes, an intricate problem. The existence of involutional melancholia does not rule out the possible presence of the widest variety of structural pathology. The review of a large number of patients clearly indicates that it is often

THE PRESENT STATUS OF SURGICAL PROCEDURES DIRECTED AGAINST THE EXTRAPYRAMIDAL DISEASES

RUSSELL MEYERS, M.D., F.A.C.S., Brooklyn

FROM the therapeutic standpoint, the disease processes commonly attributed to dysfunction of the extrapyramidal system are among the most refractory of all conditions with which the neurologist is required to deal. This group of disorders is protean in its manifestations, encompassing a variety of clinical syndromes, the outstanding characteristics of which are hyperkinesia and alterations in myotonus. Among them may be listed the familiar syndromes of athetosis, chorea, dystonia musculorum (torsion spasm, tortipelvis), and paralysis agitans (parkinsonism); a heterogeneous series in which are represented tics and spasms (e.g., facial tic, spasmodic torticollis), myoclonus, paramyoclonus multiplex, hemiballismus, hiccup of central origin, and certain types of cerebral spastic palsy; and a number of relatively rare conditions such as Wilson's progressive hepatolenticular degeneration, Westphal and Strümpell's pseudosclerosis, Jakob and Creutzfeldt's spastic pseudosclerosis, C. Vogt's status marmoratus and Hallervorden and Spatz's status dysmyelinisatus of the globus pallidus. The syndrome most recently added to the catalogue of extrapyramidal diseases is that described by Mount and Reback⁴⁸ under the name of familial paroxysmal choreo-athetosis.

The generally disappointing character of the conservative measures employed against these disorders is too well known to require more than a passing reference here. Under one circumstance or another almost every agent in the pharmacopoeia has been empirically subjected to trial, and physical, re-educational, and psychiatric measures of diverse sorts have been employed without favorably influencing the vast majority of patients afflicted with the so-called extrapyramidal diseases.

In brief summary it may be indicated that certain cases of parkinsonism appear to be partially benefited by the belladonna derivatives,^{2, 14, 15, 16, 23, 27, 32, 33, 45, 50, 51, 52, 54, 65, 66, 72^a, 72^b, 73^b, 74} vitamin B₆,^{34^a, 34^b, 69} benzedrine sulfate,^{11, 13, 44, 59, 63, 73^a} and syntropan⁶⁷ and that temporary

improvement has been observed in certain instances of dystonia and athetosis following injections of curare and its synthetic relative, erythroidine hydrochloride.⁷

Even in those cases in which therapy exerts a partial improvement, there are manifest drawbacks—viz., (a) such treatments, being symptomatic rather than curative, require to be administered throughout the lifetime of the patient; (b) the undesirable side reactions often produced by the relatively large and sustained doses of drug imply numerous contraindications; (c) the results are unpredictable from case to case; and (d) "relapses" are not unusual. With reference to the extrapyramidal disorders other than parkinsonism, dystonia, and athetosis, the therapeutic outlook is even more discouraging.

Experimental therapeutics in this field has been hampered by a number of disquieting circumstances, the most obvious among which are the following: (a) the lack of a satisfactory anatomic delineation of that which is commonly referred to as "the extrapyramidal system"; (b) confusion concerning the functions of this system and its component parts; (c) the unsolved problems of the interrelationships obtaining between the neocortex at large, the pyramidal, parapyramidal, extrapyramidal, thalamic, and cerebellomesencephalic complexes; (d) the uncertain state of knowledge concerning the seats of pathologic change in the different extrapyramidal diseases; (e) corresponding deficiencies in the comprehension of the pathogenesis of the various clinical manifestations of these diseases; (f) lack of conviction on the point that among the several clinical syndromes categorically referred to as extrapyramidal diseases there are identifiable common pathophysiologic principles of such character as to warrant their being considered together; and (g) the inability to reproduce the so-called extrapyramidal syndromes in laboratory animals.

Formidable as these difficulties are, they are further intensified by the numerous uncertainties relating to the etiology of the extrapyramidal diseases. To take as illustration that clinical entity concerning which it is generally regarded we are best informed from the etiologic standpoint—namely, paralysis

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30 1941.

From the Department of Physiology (Neurophysiology), Long Island College of Medicine, and the Neurosurgical Services of the Brooklyn and Kings County hospitals.

technic, I recognize the fact that I may live long enough to retract; yet, on the basis of considerable experience, I am mildly enthusiastic about electroshock therapy. If the preliminary examinations, particularly the cardiovascular survey and the x-ray examination of the vertebral column are carefully and thoroughly made, then the risk is slight. The clinical results have been quite good. It re-

mains to be seen whether they will survive the test of time. Electroshock therapy has definite advantages over metrazol-induced convulsive treatments. The technic is more controllable and, blessedly, the patient is at once unconscious so that he or she is spared the physical and the psychologic brutality of the convulsion.

111 North 49th Street

THE COUNTY SOCIETY SECRETARY

This is an accolade for the man who performs one of the most important but thankless jobs in medical organization—the county society secretary.

Year-end society elections throw a momentary spotlight on his position, but for the next twelve months he performs his duty in the relative obscurity of behind-the-scenes desk work. In some counties he is a veteran, re-elected year after year by his colleagues because they know he is willing to make personal sacrifices for the good of his profession. In other counties he is a newcomer, elevated to the post because the society members believe he can be relied on to carry out the organization's many paper-work details.

For the president there is limelight, prestige, and the gratification which comes from being the key man in local medical affairs for a brief time. For councilors and committee chairmen there are questions of policy to be considered and acted upon. For the secretary there are bulletins from the State Association to be transmitted; there is correspondence with the State Association and the *Journal* to keep up; there are membership records to keep straight.

In terms of telephone communications the secretary's job is like a switchboard. Through it passes the vital business which keeps the society alive. Through it the wires are kept clear and traffic is kept moving. It is not a job on which lip service is of much value. The man who fills this job deserves the complete cooperation of all members of his society.—*Ohio State Med. J.*

FITNESS FOR FREEDOM....

... is the theme of a special March number of the *Survey Graphic* in which such eminent leaders as C. E. A. Winslow, Howard W. Haggard, Haven Emerson, Frank G. Boudreau, Thomas Parran, Donald B. Armstrong, and others tell:

- about contrasts between health provisions for the armed services and civilians.
- what you should know about nutrition.
- about alcohol in wartime.
- how to select a physician and a dentist.
- how we can advance medical care.
- what we can learn from Britain about the welfare of women and children in wartime.
- how we can reduce venereal disease in the armed services and in war-production areas.
- changes rationing may bring to food, clothing and shelter.
- how we can rehabilitate rejected men.
- what physicians and laymen should know about mental health.
- how we must prepare to combat epidemics.
- why we must have a national program for buoyant health.
- how Americans should plan vacations in 1942.
- what business can do to keep employees healthy.
- how we can improve our public health services.
- about medical services every family must have.
- who should organize a group health plan.
- about the future of voluntary hospitals.
- what health experts see on world horizons.
- what the future of American health demands of physicians and citizens generally.

PULLMAN CARS INTO HOSPITALS

The War Department is converting four Pullman cars into hospital ward cars at a cost of \$22,556 each. Each car will have beds for 32 patients. Two of these cars will be used with each hospital train. An administrative unit car will have an operating room, kitchen capable of feeding 500, bunks, shower for kitchen personnel, and office and quarters for the two officers in charge. Each ward car will have three nurses and three orderlies.—*Wichita Medical Bulletin*

REBUKE

Why don't yer print me pome?
Ye've had it long enough;
It's better by far I'm tellin' yer
Than lots of yer printed stuff.
So scabble around and find it—
And don't let it happen agin!
When yer see me name to a pome
I expect yer to put it in.

—Edna Moore Adams, "Sun Dial,"
New York Sun

a similar operation to advantage on 2 additional cases.

In 1910 Anschütz¹ recorded a successful experience in the treatment of choreo-athetosis by ablation of the motor cortex and, since then, reports of the results of cortical operations in the hands of Payr, Nazaroff, Polinow, Bucy, Sachs, Walker, Bailey, Putnam, and Klemme have appeared.

In the first of a series of 9 cases Bucy⁶ extirpated that portion of Brodmann's area 6 considered to correspond to the projections of the hand and forearm. The athetoid movements were abolished and have not reappeared throughout the nine years since operation. The procedure is stated to have produced a slight increase in the severity of a pre-existing hemiparesis. A similar surgical procedure was carried out in the second and third cases of the series.^{6a, 6b} Although the choreo-athetosis in both instances was appreciably dampened, it was not entirely abolished, and for this reason in his next 5 patients Bucy^{6b} resected area 4 as well as area 6. Two of the 5 patients presented a unilateral tremor, one of which was of post-traumatic and the other of doubtful, possibly syphilitic, origin. A satisfactory result was obtained in both tremor cases. The remaining 3 patients presented syndromes commonly designated by the terms choreo-athetosis, hemiballism, and dystonia (torsion spasm). In this group the results were disparate. An appreciable diminution in hyperkinesia was obtained in 2 cases, but in the third case—that of a patient with bilateral dystonic movements—no benefit was obtained even though areas 4 and 6 of both hemispheres were eventually extirpated.

Considerable importance is attached to the ninth case cited in Bucy's report^{6b}—a patient from whose left lateral occipital region Bailey removed a posttraumatic cortical scar. No benefit resulted from this operation. The experience suggests that improvement is not to be anticipated by the mere surgical removal of an obvious lesion, and it demonstrates that the clinical improvement that follows precentral cortical extirpation is not properly explicable in terms of "diachisis," "equipotential function," or other nonspecific effect.

In 1935 Sachs³ reported favorably on the results of removal of the precentral gyrus in 3 cases of choreo-athetosis.

By far the largest series of cases subjected to cortical extirpation is that reported upon by Klemme,^{6a-c} whose experience now exceeds 100 patients. Instances of parkinsonism, as well as dystonia musculorum and choreo-athetosis, were included in this report. It is not entirely clear from Klemme's paper whether or not closely corresponding areas of cortex were regularly removed in all cases of the series, but the surgical attack in the main was directed at the precentral cortex, more particularly at area 6. Measured by the effect on the hyperkinetic phenomena, a

number of strikingly good results were obtained in Klemme's series.

It should be recorded that some writers have failed to influence favorably the movements of choreo-athetosis and dystonia by resection of the precentral cortex. Among these are Davison and Goodhart,¹² Foerster,^{13b} and Klemme.^{40c} Recently, a girl, aged 17, with a left-sided choreo-athetosis of eight years' duration was operated upon by Dr. E. Jefferson Browder. An extensive block of cortex, representing effectually all of area 6 anterior to the precentral gyrus, area 8, and portions of areas 9 and 46, was extirpated from the right hemisphere. Area 4 and a narrow strip of area 6 adjacent to it were left intact. The operation was followed by a hemiplegia and, during the ten days that this condition prevailed, hyperkinesia was absent. As the paralysis receded the athetoid movements returned with their former vigor and, indeed, became more severe in respect to frequency and amplitude.

Mashanskij⁴² failed to obtain satisfactory results in the treatment of hyperkinesia by injection of alcohol into the motor and premotor cortex, by subcortical section of the pyramidal tract, and by partial section of peripheral nerves. Naffziger⁴³ recorded improvement in 1 out of 4 patients subjected to alcohol injection of the precentral region.

Reports on the effect of tenotomy and section of peripheral nerves for choreo-athetosis are uniformly disappointing. Such procedures are open to the criticism that they ignore the actual problem of dynamic neural equilibrium and attack it as if it were one of the actions of the final common pathway and the corresponding muscles.

(b) *Cordotomy.*—In 1931 Putnam^{57a} carried out the first anterolateral cordotomy for the relief of athetosis. The series now exceeds 30 cases, of which nearly half presented with bilateral involvement.^{57b, 57c, 57d, 57e} It is the intention of the operation, in effect, to interrupt the so-called extrapyramidal bundles—i.e., the rubrospinal, reticulospinal, tectospinal, olivospinal, and vestibulospinal tracts. Unless the lower extremity alone requires treatment, the level of choice for the surgical section is at the second cervical segment. Of the first 27 cases, all with advanced hyperkinesia, 20 showed appreciable degrees of postoperative improvement in that their aberrant movements were now less vigorous. Motor control was correspondingly increased and speech was more easily understandable. Some patients gained the ability to sit up alone in a chair and a few were able to walk. In general, the patients were more comfortable physically, enjoyed a brighter psychologic outlook, and were capable of being more readily handled by their attendants. Oldberg⁵⁸ carried out the operation of anterolateral cordotomy on 10 cases and reported a marked diminution in the extraneous movements, reduction in spasticity, when present, and relief from pain.

(c) *Pallidofugal Section.*—The present writer

"agitans"—we find ourselves under the present necessity of referring to "postencephalitic," "arteriosclerotic," and "idiopathic" (sic) types. The solution of the etiologic and pathogenic issues is to a considerable extent quibbled by the fact that the psychologic processes of attention and emotion are singularly capable of influencing the clinical manifestations of the extrapyramidal diseases. Indeed, several of the disorders under inquiry appear to stand on the precarious borderland between what are traditionally represented in neurology as "organic" and "functional." Thus, until fairly recently, athetosis, torticollis, tremors, tics, and dystonic and choreiform movements were quite universally interpreted as psychoneuroses, and even today psychoanalysis and other psychotherapeutic measures are the procedures of choice in the judgment of some therapists. It must be conceded that the therapist often encounters among the major hysterias close simulacra of the extrapyramidal disorders. The total effect of the difficulties referred to above has been to keep the *modus operandi* of experimental therapeutics at a primitive and empiric level.

Within the past decade several surgical forays have been made to deal with the extrapyramidal diseases and some encouraging results have been obtained, particularly in choreo-athetosis, dystonia musculorum, and parkinsonism. To a smaller extent, the therapeutic problems presented by tics, spasms, myoclonus, intractible hiccup, and cerebral spastic palsy have also been attacked by surgical methods. While it is to be recognized that these endeavors are as yet in the experimental stage, that uniformity of results is not yet been realized, and that the matter of standardization of the operative procedures is only now beginning to take form, a considerable interest in the work has apparently been aroused and inquiries bearing on its possibilities have been numerous.

In view of this, it is the intention of this communication to consider the present status of those procedures that have been found useful in the treatment of the extrapyramidal disorders and to outline their indications, contraindications, limitations, hazards, and relative merits. Operative procedures that have proved ineffective will be referred to only insofar as the negative findings arising from them contribute to an interpretation of the physiologic dynamics of the disorders for which they were intended.

I. Choreo-Athetosis and Dystonia Musculorum

The etiologic processes generally considered to subtend these disorders are the encephalitides and meningitides, cerebrovascular accidents, craniocerebral trauma, and the cerebral abiotrophic and degenerative diseases. In accord with the arguments advanced by Wilson⁷⁵ that the syndromes referred to as chorea and athetosis are merely variants of one another, the two will be dealt with here under a joint heading. For a similar reason and since various types of hyperkinesis clinically designated by such terms as torticollis, ballismus, spasms, grimacing, torsion of the trunk, etc., either frequently coexist with, or actually represent, special instances of choreiform and athetoid movements, it will be convenient to consider the surgical therapy of the dystonias along with that of choreo-athetosis.

Evidence from several experimental sources^{20, 26, 23b, 70, 75} strongly indicates that in the movements of chorea and athetosis (and probably also of dystonia) antagonistic muscle groups are activated without regard to the physiologic principles of reciprocal innervation and, further, that muscles which under normal conditions act synergically with respect to one another often contract and relax independently. In contrast, the tremors of paralysis agitans are characterized by an agonistic-antagonistic muscle activity that proceeds wholly in accord with the principles of reciprocal innervation.^{23a} The obvious inference is that the neural mechanisms underlying the hyperkinetic phenomena of choreo-athetosis and parkinsonism differ from each other in certain crucial respects. As we shall see, the evidence from experimental surgery supports this deduction in a convincing manner.

(a) *Cortical Operations.*—Sir Victor Horsely²² was apparently the first to carry out a successful surgical procedure for the relief of athetosis. His patient was a boy, aged 15, who at the age of 8 years suffered an attack of scarlet fever complicated by a left hemiplegia. The hemiplegia partly regressed, but there shortly supervened a severe athetosis of the left upper extremity. At operation, a marked atrophy of the right postcentral gyrus was observed. Horsely resected the precentral gyrus corresponding to the projection of the upper extremity, and the aberrant movements promptly disappeared. A considerable degree of enduring dyspraxia of the affected limb followed the operation, but throughout the follow-up period of fourteen months no athetoid movements were observed. Horsely carried out

the intracranial procedures may be expected to carry a greater mortality than the intraspinal procedures. In Klemme's series of 97 cases the mortality was slightly over 17 per cent. In Putnam's report of his first 27 cases the mortality was 11 per cent. Oldberg carried out antero-lateral cordotomy on 10 cases without a death. These are the only series large enough to be significant for statistical purposes. In all likelihood as experience grows the mortality can be reduced to the neighborhood of 4 to 5 per cent.

Morbidity is essentially that to be anticipated in neurosurgical procedures in general, since the same exposure to the possibilities of wound infection, osteomyelitis, postoperative hemorrhage, meningitis, and brain abscess, however small, is here involved. Under no circumstances should operation be carried out through skin affected by eczema or acne. The aspiration of vomitus and hypostatic congestion, which are occasionally responsible for postoperative bronchopneumonia, are factors to be considered and guarded against. Hyperthermia, a common neurosurgical complication, is an additional factor in morbidity, and Klemme's experience has indicated to him the necessity of deferring operation during the summer months. The operation of high cervical cord section always carries with it the likelihood of severe respiratory embarrassment. For this reason, the surgeon who contemplates antero-lateral cordotomy lists among his indispensable armaments endotracheal anesthesia, oxygen, and a Drinker respirator.

II. Paralysis Agitans

Thus far, three levels of the nervous system have been surgically attacked with some measure of success in the effort to control the hyperkinesis of paralysis agitans—viz., (a) the spinal cord, (b) the precentral cerebral cortex, and (c) the basal ganglia. The data derived from these sources have yielded a considerable body of pathophysiologic information bearing on the neural mechanisms of parkinsonism. In addition, valuable information of a negative sort has been acquired by the parallel demonstration that the tremor of parkinsonism cannot be abolished by (a) interruption of the posterior roots of the spinal nerves innervating the affected limb(s) (Pollock and Davis,⁵⁶ Puusepp,^{55a} and Foerster and Gagel⁷²); (b) section of the antero-lateral columns (Putnam^{57c, 57f, 57g} and Oldberg⁵³); (c) section of the dorsal columns (Puusepp^{55b} and Rizzatti and Moreno⁵⁰); and (d) destruction of the dentate nucleus (Delmas-Marsalet and van Bogaert¹³). Seemingly, some diminution in rigidity can be accomplished by each of these measures even though the tremors themselves are unaffected.

(a) *Cortical Operations.*—As heretofore noted, Bucy^{4b, 6b} reported favorably on the abolition of hyperkinesis in 2 cases of unilateral tremor following the extirpation of areas 4 and 6. His first case presented tremors of the action and intention types, as well as those at rest. The etiology in this instance was trauma. His second case was more readily comparable in its clinical features to the familiar parkinsonian picture. Although the presence of syphilis in this instance was revealed by serologic tests, the etiology of the unilateral tremors was uncertain. It should be commented in passing that the distinctions formerly presumed to exist between the action, intention, and rest types of tremor do not appear wholly warranted upon close analysis. In many "classic" cases of parkinsonism, tremors may be discovered not only at rest but also during intentional action.

Klemme's results in the treatment of paralysis agitans by resection of area 6 have been considered highly favorable. Concerning the degree of improvement, this author^{4b} has asserted: "It suffices that these patients are rehabilitated and can carry on their former work." He has encountered no recurrences since the first case was operated upon in 1937.

(b) *Cordotomy.*—Following his failure to influence the tremors of hemiparkinsonism by antero-lateral cordotomy, Putnam^{57c, 57f, 57g} was led to suppose that the impulses producing the tremors of paralysis agitans travel largely in the lateral funiculus of the cord, particularly in that region which gives transit to the crossed pyramidal tract. Accordingly, he interrupted the lateral pyramidal tract at the second cervical level in 6 cases of unilateral parkinsonism. The results were reported upon in 1940 and may be summarized as follows. When the section is sufficiently complete, there is an appreciable dampening of the tremors so that in the resting state they are barely if at all perceptible. During the execution of voluntary acts and under emotional excitation tremors may be evident, although of less amplitude than noted preoperatively. Rigidity is effectually abolished but is replaced by a slight antigravity spasticity.

Mashanski,⁴³ following Putnam's earlier lead, employed the operation of antero-lateral cordotomy in 17 cases of alternating tremors and other adventitious movements. He reported 3 apparent permanent recoveries and 5 "fairly satisfactory" results. It is difficult, in view of Putnam's negative results in 5 successive cases of hemiparkinsonism subjected to antero-lateral cordotomy, to account for Mashanski's successes unless the pyramidal tracts in these instances were incidentally damaged.

(c) *Operations at the Level of the Basal Ganglia.*—In a recent article the present writer^{4b} reported in detail experiences with 8 cases of paralysis agitans subjected to various operative procedures on the basal ganglia. The series at present numbers 10, of which 5 were unilateral

recently attempted to abolish a unilateral choreo-athetosis of the right-sided extremities in a girl, aged 17, by sectioning the fibers of the left ansa lenticularis and fasciculus lenticularis. During the early postoperative days, while a condition of hemiparesis prevailed, the patient was free of aberrant movements. As recovery took place, however, the athetotic movements returned.

The Present Surgical Outlook

This requires a consideration of the operations directed against choreo-athetosis and dystonia musculorum from the standpoints of (a) applicability, (b) the degree and duration of improvement to be anticipated, (c) the untoward neurophysiologic side effects involved, and (d) mortality and morbidity.

(a) *Applicability.*—The operative procedures thus far employed to advantage are manifestly of a serious character and are, therefore, contraindicated for all patients whose general constitutional or specific organic status is such as to render them poor risks for any elective surgery. This eliminates the majority of elderly patients, young children, and those of other age groups depleted from any cause. In the opinion of the present writer, those patients presenting clinical evidence of vegetative dysfunction should also be eliminated. It would seem equally unjustified to recommend operation for those who present aberrant movements of only slight to moderate degrees of severity, particularly if the affected limbs possess useful function in terms of motor power, coordination, and eupraxia.

A consideration of the applicability of surgery to bilateral cases involves a comparison of anterolateral cordotomy with the cortical procedures. With respect to the former, Putnam has operated on a sufficient number of patients to demonstrate its feasibility. He has been impelled to recommend, by virtue of the serious respiratory embarrassment encountered in some of his earlier one-stage operations, that the bilateral procedure be carried out in two stages. With respect to the cerebral operations, both Bucy and Putnam have voiced the opinion that cortical ablation is not adapted to bilateral cases because of the grave motor deficiencies likely to be produced thereby. Klemme, however, has not hesitated to deal with bilateral cases. A detailed description of his end results in such cases is not available as yet. It is Klemme's present conviction that the bilateral procedure should be carried out in two stages.

(b) *Degree and Duration of Improvement.*—In anticipating the end result for a given surgical candidate, it must be borne in mind that failure in some instances to influence favorably the hyperkinesia has been recorded for both the cord and cortical operations. Within the next few years there will probably be realized a greater

acumen in the selection of cases and a more precise standardization of operative procedure so that frank failures will diminish in number. Meanwhile, it is fair to expect that the majority of patients will enjoy some degree of improvement—in Putnam's^{7b} words, "from slight to considerable." Social and economic rehabilitation cannot fairly be anticipated, although an occasional case may prove to be so restored. The likely duration of improvement is, at the present time, difficult to evaluate, since a sustained follow-up has been possible in only a few cases. Evidently, some of the cases subjected to cortical extirpation are enduringly benefited. In others, an initial improvement has given way to a recurrence. Following anterolateral cordotomy, a period of complete absence of extraneous movements is usually enjoyed, but there is apparently a tendency for the movements to return within three to six months and after a year or two they may be nearly as severe as before operation. In Oldberg's³³ opinion, extrapyramidal cord sections do not produce permanent results.

(c) *Untoward Neurophysiologic Side Effects.*—Following the extirpation of a portion of the precentral cortex a period of hemiplegia usually supervenes and, if the dominant hemisphere is attacked, aphasia also presents. In some instances epileptiform convulsions have been observed (Bucy, Klemme) during the first and second postoperative weeks. Fortunately, these are usually not permanent sequelae, although the possibility that they may prove so in an occasional case must be entertained. A frequent residuum lasting well beyond the first and second years after operation is a slight to moderate degree of spastic hemiparesis characterized by hyperreflexia and the usual upper motor neuron signs. The most common enduring sequel is a moderate to severe degree of dyspraxia. However, the disability involved here is often subjectively preferable to the ceaseless adventitious movements. As yet we do not possess dependable data concerning the effect of cortical ablation (particularly in bilateral cases) on the intellectual functions. Theoretic considerations would lead one to expect a measurable degree of dementia, but only properly conducted preoperative and postoperative intelligence tests will permit a valid answer to this important question.

Following anterolateral cordotomy, there is an initial flaccid paralysis that usually implicates the sphincters, as well as the somatic motor functions. Within two to three months the motor status usually returns to its preoperative level and then the only significant permanent residua are the deficiencies of thermal and nociceptive sensations consequent upon damage to the lateral spinothalamic tract. Aphasia, convulsions, and intellectual deficits are, of course, not involved in the cord section.

(d) *Mortality and Morbidity.*—In general.

ing operation, the more enduring sequelae become apparent—namely, dyspraxia and a moderate degree of spastic hemiparesis characterized by loss of arm swing and circumduction of the affected lower extremity in walking. Because of this circumstance, Bucy considers bilateral cortical extirpation to be hardly justifiable. It is nevertheless surprising to discover how considerable is the degree of “voluntary control” that can be regained in the human (by comparison, e.g., with the monkey) after resection of portions of areas 4 and 6.

The previously made comments bearing on the matters of postoperative convulsions and intellectual deficits following cortical extirpation for choreo-athetosis and dystonia are equally applicable in our present consideration.

Two of Mashanski's⁴³ patients were left with permanent Brown-Sequard syndromes following anterolateral cordotomy.

Following lateral pyramidal cordotomy, an initial flaccid paralysis is gradually replaced by a more lasting spastic paresis of the limbs of the homolateral side. The gait is characteristically hemiparetic. Clonus may be demonstrable at the wrist, knee, and ankle. Although the motor power of the affected limbs is reduced to between one-half and two-thirds its preoperative status, the patients are able, according to Putnam, to move the fingers individually and to write, dress, and feed. They are, however, dyspraxic for skilled acts of the more complicated sort. Aside from the described motor changes, sensory disturbances in the nature of temporary hypalgesia, hypesthesia, and dysesthesia may appear.

In the light of most traditional teachings, the recovery of the degree of motor function noted following lateral pyramidal section is distinctly unexpected. The subhuman experiments of Tower,⁷¹ Rothmann,⁶¹ and others, however, clearly demonstrate that “voluntary” impulses, in addition to being mediated over neural pathways in and near the pyramidal tracts, must also travel over other cord pathways.

The operations on the basal ganglions may be carried out without producing enduring alterations of motor, coordinative, eupraxic, sensory, speech, or intellectual functions.^{47a, 47b} This is perhaps the chief virtue of this method of surgical attack.

(d) *Mortality and Morbidity.*—Of the 17 cases subjected to anterolateral cordotomy in Mashanski's series, 3 (17.5 per cent) died. The mortality for the operation of lateral pyramidal cordotomy in Putnam's hands has been, thus far, nil. Klemme's figures of 17 per cent mortality for the operation of cortical extirpation have already been cited. There have been 2 deaths in the present writer's series. Both occurred in patients with advanced bilateral parkinsonism. The first of these had as one of his symptoms a severe dysphagia that was manifestly responsible for the aspiration of vomitus on the operating table. A bronchopneumonia led to this patient's

death on the eighth postoperative day. The second case died of bronchopneumonia two months following operation. In all likelihood, the mortality figures can and will be appreciably reduced for all three operations as a better selection of cases becomes possible and as experience widens in the technical execution of the procedure. It is likely, however, that the operations on the basal ganglions will continue to be the most formidable.

With respect to morbidity, there is little to comment beyond what has already been considered in connection with choreo-athetosis and dystonia. The matter of respiratory embarrassment does not appear so serious a threat following lateral pyramidal cordotomy as following anterolateral cordotomy. In the operations on the basal ganglions, in spite of the drainage of cerebrospinal fluid and operative insult to tissues close to the hypothalamic nuclei, no physiologic disturbances other than those routinely met following intracranial procedures have been encountered.

III. Tics, Spasms, Myoclonus, Intractable Hiccup and Spastic Palsy

As previously indicated, it is doubtful whether the notion that these conditions are extrapyramidal diseases can be substantiated. However, inasmuch as they are so considered by some writers, their surgical therapy will be briefly dealt with here.

Since 1890, facial tics and other facial spasms—unilateral and bilateral—have been treated by interruption of the seventh nerve in its extracranial course.^{9, 21, 25, 39, 41, 64} The resulting facial palsy, although itself disfiguring, appears to be preferred by some patients to the involuntary grimaces.

Little success has attended the numerous efforts to treat spasmodic torticollis by sternomastoid tenotomy, cervical plaster casts, multiple myotomy, and other orthopaedic measures.¹⁷ Since Keen's³⁷ report in 1891, however, this condition has been frequently treated^{10, 17, 22, 31, 42} by interruption of the spinal accessory nerve and section of the dorsal and/or ventral roots of the upper three cervical nerves. Although the procedure implies a rather considerable postoperative motor deficit and is not uniformly successful in its end results, it is seemingly the most effective of the several operations advocated for spasmodic torticollis. Later workers have modified the procedure in certain minor respects—e.g., by cutting the eleventh nerve intramenigeally⁴² rather than extracranially and by injecting alcohol into the nerve trunks rather than anatomically dividing them. The procedure has been advantageously employed

and 5 were bilateral cases. Altogether, 13 operations have been carried out on these patients: extirpation of the head of the caudate nucleus in 3 instances;^{3,47a} extirpation of the head of the caudate nucleus and interruption of the fibers coursing in the oral half to three-fourths of the anterior limb of the internal capsule in 4 instances; extirpation of the head of the caudate nucleus and oral thirds of the putamen and globus pallidus (Crus II) and interruption of the fibers running in the oral fourth of the anterior limb of the internal capsule in 1 instance; and section of the pallidofugal fibers (ansa lenticularis, fasciculus lenticularis, and "fine fibers" of Papez) in 5 instances. For each of these procedures it has been possible to demonstrate an obvious improvement with respect to tremors and rigidity. The qualifications bearing reference to their relative merits will be dealt with shortly. In general, however, the procedure of pallidofugal section, aside from being technically the simplest of the operations on the basal ganglia and the most susceptible of standardization, is seemingly the most effective. By this procedure tremors may be entirely abolished or reduced to a slightly perceptible degree, and the rigidity factor may be reduced from one-half to one-third of its previous level. There is observable a corresponding improvement in eupraxic functions and in automatic associated acts.

In the case subjected to extirpation of portions of the caudate nucleus, putamen, and globus pallidus, both the unilateral tremors and a severe festination were abolished. A monoplegia of the left upper extremity supervened following this operation, seemingly the result of damage to the blood supply of the genu of the internal capsule as it traverses the bed of the putamen. From this monoplegia the patient has been making a steady and effective recovery, although a paresis is still evident. For this reason it has been deemed unwise to employ this particular procedure in subsequent cases.

The Present Surgical Outlook

The operations directed against paralysis agitans will be considered under the same headings as those used in connection with choreo-athetosis and dystonia.

(a) *Applicability.*—Much that has been observed in our earlier generalizations on the applicability of surgical measures to cases of choreo-athetosis and dystonia holds with equal validity in connection with paralysis agitans and therefore requires no reiteration here.

With reference to bilateral cases, it would seem equally feasible to employ section of the lateral pyramidal tract, cortical ablation, or section of the pallidofugal fibers. A two-stage operation is clearly indicated for the cortical procedure. It may, however, ultimately prove practicable to execute the operation of bilateral pyramidal tract section and of bilateral pallidofugal section

in one stage. Putnam has not as yet applied the pyramidal section to bilateral cases. In a single case the present writer sectioned the pallidofugal fibers bilaterally at one procedure. Unfortunately, this patient died on the eighth postoperative day of an aspiration pneumonia, so that while the relation of the particular operative procedure to the end result in this instance is dubious it is not possible to subscribe without reserve to the propriety of doing both sides at once. For the present a two-stage procedure seems indicated.

(b) *Degree and Duration of Improvement.*—

In general, it is reasonable to anticipate an appreciable degree of improvement, if not effectual abolition, of the tremors of paralysis agitans following the application of each of the three operative procedures described. Rigidity also may be expected to diminish. Economic and social rehabilitation has been realized in a few cases, but it is not regularly to be anticipated. It must be recognized that for each operation improvement has not been achieved in certain cases. Thus, Mashanskij⁴⁸ recorded 7 failures following anterolateral cordotomy. Putnam⁴⁹ found it necessary to reoperate upon some of his cases because the original section of the lateral pyramidal tract did not appear to be deep enough. A proper future standardization of procedure will undoubtedly eliminate this circumstance. Putnam has also reported failure favorably to modify alternating tremors in 1 case subjected to extirpation of area 8 of the precentral cortex. In addition, he has cited failures by cortical extirpation in the hands of White and of Sussmann. Among the writer's cases subjected to operations on the basal ganglia, 1 patient presenting a severe bilateral parkinsonism eventually proved to be a therapeutic failure. Following extirpation of the head of the right caudate nucleus, this patient enjoyed for over three months a marked reduction in the tremors and rigidity of the left-sided limbs. When the head of the left caudate nucleus was extirpated, however, not only did the tremors of the right side continue unabated but those of the left side reappeared, although never quite reaching their former vigor.

It is not to be anticipated that tremors of the head, jaw, and tongue will be influenced by lateral pyramidal cordotomy.

Insofar as permanency of improvement is concerned, little can be said at present in view of the fact that not sufficient time has elapsed to permit a proper follow-up. Initial improvement has been maintained for as much as two or more years in several of the older cases in each operative series.

(c) *Untoward Neurophysiologic Side Effects.*

Following the extirpation of portions of the precentral cortex, a contralateral hemiplegia usually supervenes. If the dominant hemisphere is attacked, aphasia is to be expected. As these conditions recede during the early weeks follow-

"due to" disease of the basal ganglions. We do possess information, however, that allows us to regard the neural circuits of choreo-athetosis as passing through the precentral cortex (whatever the origin of the abnormal impulses) and, without availing themselves of the pallidofugal system, as reaching their final common pathways by way of the anterolateral columns of the cord. By contrast, the impulses mediating the tremors of parkinsonism may be conceived of as passing through the precentral cortex (whatever their origin), coursing along the fibers in the anterior three-fourths of the anterior limb of the internal capsule; implicating—in a manner not yet clearly understood—the caudate nucleus, putamen, and globus pallidus; passing along the pallidofugal fibers; and reaching their final common pathways by way of the pyramidal tracts or other fibers running in close anatomic relation to them.

by Putnam^{57d,57e} as a supplement to anterolateral cordotomy in the treatment of those cases of athetosis and dystonia presenting extraneous movements of the neck as well as of the trunk and extremities.

An occasional sequel to encephalitis is encountered in the form of a severe and uncontrollable hyperkinesia of the tongue (e.g., myoclonus). Ingebrigsten⁵⁵ recently reported on a case in which an almost complete abolition of the aberrant tongue movements was achieved by loosening the genioglossus muscles from their attachments to the mandible.

Intractable hiccup, also an occasional complication of, or sequel to, encephalitis, has been successfully dealt with by phrenicectomy and phrenicexeresis.^{5,36,55} The operation may be carried out unilaterally or bilaterally and in most instances with a reasonable expectancy of success.

Certain of the syndromes loosely referred to as cerebral spastic palsies appear to be benefited by the operation of dorsal rhizotomy as advocated by Foerster.^{19a} The rationale of this procedure rests on the concept that the spastic state of the affected muscles is in part maintained by the proprioceptive impulses recruited from the contracting muscles and stretched tendons themselves. The "cutting down" of these centripetal kinesthetic impulses by dorsal root section reduces the neural discharges along the corresponding final common pathways and so mitigates the muscle spasm. Unfortunately, other sensory modalities than proprioceptive must be incidentally sacrificed by dorsal rhizotomy and, inasmuch as motor control is so largely dependent upon afferent impulses, it, too, necessarily suffers from the procedure of rhizotomy. It is none the less highly valuable, particularly in those cases where the contractures are painful, to be able to resort to Foerster's procedure. A warning against too extensive resection of dorsal roots is in order lest the patient be exposed to dangers of serious trophic skin changes.

It has been demonstrated that the operation of sympathetic ramisectomy, first advocated by Hunter^{30a-c} and Royle⁶² in the treatment of spastic palsy, rests on false theoretic premises and that it is for practical purposes wholly ineffective. In addition, Bucy^{4a} has shown that spastic paraplegias in man cannot be favorably modified by ventromedian (vestibulospinal) cordotomy.

Insofar as mortality and morbidity are concerned, all the operative procedures referred to under the present heading may be

carried out with relative impunity. The greatest disadvantage attaching to them is the incidental sacrifice of motor, sensory, and coordinative functions.

The Pathophysiologic Mechanisms of Choreo-Athetosis and Paralysis Agitans

The data derived from a study of patients subjected to the various operative procedures listed above make it clear that the neural mechanisms subtending choreo-athetosis on the one hand and parkinsonism on the other are quite distinct. Thus, anterolateral cordotomy is effective for the former but ineffective for the latter; pallidofugal section is effective for paralysis agitans but ineffective for choreo-athetosis. It is equally clear that many of the "release" hypotheses of the pathogenesis of chorea, athetosis, and paralysis agitans are untenable, inasmuch as the operations in which parts of the caudate nucleus, putamen and globus pallidus, and section of the pallidofugal fibers are removed do not result in the "escape" of lower motor mechanisms manifest as hyperkinesia. Confirmation of the latter observations in the human is to be found in Kennard's³³ work on the basal ganglions of the monkey.

The only region at which both disease processes have been demonstrated to share common anatomic ground is at the cortical level. This is not surprising, however, when it is reflected that the cortex of the telencephalon represents the dominant pole of all physiologic gradients and that disruption of functional patterns at this level is regularly followed by a neural dysequilibrium of patterns (whether physiologic or pathologic) at other levels. Nothing in the data at present available permits us to say that the hyperkinesia of choreo-athetosis or of paralysis agitans takes its origin from the cortex. The most that may be said is that the neural circuits operating to produce these extraneous movements are in part mediated by the precentral cortex and that they are in this sense dependent to a considerable degree upon the integrity of the precentral cortex. Furthermore, presumptive evidence derived from the study of the electric potentials of the caudate nucleus in parkinsonism is at hand to indicate that the tremors of paralysis agitans do not originate in this structure.^{4b} The weight of pathologic evidence to the contrary notwithstanding, we do not at present possess data of a sort which permits the unequivocal assertion that the manifestations of parkinsonism are

"due to" disease of the basal ganglions. We do possess information, however, that allows us to regard the neural circuits of choreo-athetosis as passing through the precentral cortex (whatever the origin of the abnormal impulses) and, without availing themselves of the pallidofugal system, as reaching their final common pathways by way of the antero-lateral columns of the cord. By contrast, the impulses mediating the tremors of parkinsonism may be conceived of as passing through the precentral cortex (whatever their origin), coursing along the fibers in the anterior three-fourths of the anterior limb of the internal capsule; implicating—in a manner not yet clearly understood—the caudate nucleus, putamen, and globus pallidus; passing along the pallidofugal fibers; and reaching their final common pathways by way of the pyramidal tracts or other fibers running in close anatomic relation to them.

by Putnam^{57d, 57e} as a supplement to anterolateral cordotomy in the treatment of those cases of athetosis and dystonia presenting extraneous movements of the neck as well as of the trunk and extremities.

An occasional sequel to encephalitis is encountered in the form of a severe and uncontrollable hyperkinesia of the tongue (e.g., myoclonus). Ingebrigtsen⁵⁸ recently reported on a case in which an almost complete abolition of the aberrant tongue movements was achieved by loosening the genioglossus muscles from their attachments to the mandible.

Intractable hiccup, also an occasional complication of, or sequel to, encephalitis, has been successfully dealt with by phrenicectomy and phrenicexeresis.^{5, 36, 55} The operation may be carried out unilaterally or bilaterally and in most instances with a reasonable expectancy of success.

Certain of the syndromes loosely referred to as cerebral spastic palsies appear to be benefited by the operation of dorsal rhizotomy as advocated by Foerster.^{15a} The rationale of this procedure rests on the concept that the spastic state of the affected muscles is in part maintained by the proprioceptive impulses recruited from the contracting muscles and stretched tendons themselves. The "cutting down" of these centripetal kinesthetic impulses by dorsal root section reduces the neural discharges along the corresponding final common pathways and so mitigates the muscle spasm. Unfortunately, other sensory modalities than proprioceptive must be incidentally sacrificed by dorsal rhizotomy and, inasmuch as motor control is so largely dependent upon afferent impulses, it, too, necessarily suffers from the procedure of rhizotomy. It is none the less highly valuable, particularly in those cases where the contractions are painful, to be able to resort to Foerster's procedure. A warning against too extensive resection of dorsal roots is in order lest the patient be exposed to dangers of serious trophic skin changes.

It has been demonstrated that the operation of sympathetic ramisectomy, first advocated by Hunter^{59a-c} and Royle⁶² in the treatment of spastic palsy, rests on false theoretic premises and that it is for practical purposes wholly ineffective. In addition, Bucy⁴⁹ has shown that spastic paraplegias in man cannot be favorably modified by ventromedian (vestibulospinal) cordotomy.

Insofar as mortality and morbidity are concerned, all the operative procedures referred to under the present heading may be

carried out with relative impunity. The greatest disadvantage attaching to them is the incidental sacrifice of motor, sensory, and coordinative functions.

The Pathophysiologic Mechanisms of Choreo-Athetosis and Paralysis Agitans

The data derived from a study of patients subjected to the various operative procedures listed above make it clear that the neural mechanisms subtending choreo-athetosis on the one hand and parkinsonism on the other are quite distinct. Thus, anterolateral cordotomy is effective for the former but ineffective for the latter; pallidofugal section is effective for paralysis agitans but ineffective for choreo-athetosis. It is equally clear that many of the "release" hypotheses of the pathogenesis of chorea, athetosis, and paralysis agitans are untenable, inasmuch as the operations in which parts of the caudate nucleus, putamen and globus pallidus, and section of the pallidofugal fibers are removed do not result in the "escape" of lower motor mechanisms manifest as hyperkinesia. Confirmation of the latter observations in the human is to be found in Kennard's³³ work on the basal ganglions of the monkey.

The only region at which both disease processes have been demonstrated to share common anatomic ground is at the cortical level. This is not surprising, however, when it is reflected that the cortex of the telencephalon represents the dominant pole of all physiologic gradients and that disruption of functional patterns at this level is regularly followed by a neural dysequilibrium of patterns (whether physiologic or pathologic) at other levels. Nothing in the data at present available permits us to say that the hyperkinesia of choreo-athetosis or of paralysis agitans takes its origin from the cortex. The most that may be said is that the neural circuits operating to produce these extraneous movements are in part mediated by the precentral cortex and that they are in this sense dependent to a considerable degree upon the integrity of the precentral cortex. Furthermore, presumptive evidence derived from the study of the electric potentials of the caudate nucleus in parkinsonism is at hand to indicate that the tremors of paralysis agitans do not originate in this structure.^{47b} The weight of pathologic evidence to the contrary notwithstanding, we do not at present possess data of a sort which permits the unequivocal assertion that the manifestations of parkinsonism are

ing infection but was discontinued as the nature of the lesion became apparent.

About thirty-six hours later, the skin covering the distal two phalanges of the toe became dusky, then black. The next day the bone was exposed, which was also black. After a line of demarcation was reached, the gangrenous portion of the toe was amputated, and the patient was discharged in good condition. There was no evidence at any time of peripheral vascular disease, and there has been none since. The skin temperature of the fingers and toes is normal at the present time.

Comment

The volume of the anesthetic used (2 cc.) could not have caused undue pressure. The anesthetic was injected properly, according to aseptic technic, after a large experience in local anesthesia in the surgical clinic of a voluntary hospital. A perusal of the *Cumulative Medical Index*¹ lists many of these cases as due to the epinephrine content of this mixture when injected into the fingers and toes. These organs having end arteries and being richly supplied with autonomic nerves are sensitive to the injection of spasmogenic drugs. There is also much evidence that epinephrine lowers the oxidation of tissues nourished by vessels into which it is injected. A tissue already handicapped by infection and operation has, thus, an added load to carry.

Experimental Study

The above incident suggested that an attempt be made to see if the complication could be reproduced experimentally. In these experiments where the tails of healthy male rats were injected, the tail was assumed to be analogous in its blood supply to a finger or toe, since it also is an end organ.

Thirty male rats, each weighing approximately 250 Gm., were injected with 1 and 2 per cent procaine with and without epinephrine in the concentrations marketed, as well as with normal saline and with $1/10,000$ epinephrine. One cubic centimeter was injected with sterile precautions in the soft tissue at the base of the tail, subcutaneously, at four puncture sites around the organ, much the same as recommended for human surgery. Table 1 shows the results. Three rats were injected with each solution. None of the animals died. No cases of gangrene of the tail were found in the rats injected with either 1 or 2 per cent procaine or with normal saline. Of the remaining 21 rats, 10 developed gangrene of the tips of the tails within thirty-six hours. Several rats de-

TABLE 1

Solutions Used	Rats with Gangrenous Tails
1 per cent procaine	None
2 per cent procaine	None
Normal saline	None
1 per cent procaine, $1/100,000$ epinephrine	1
1 per cent procaine, $1/50,000$ epinephrine	2
1 per cent procaine, $1/20,000$ epinephrine	2
2 per cent procaine, $1/100,000$ epinephrine	1
2 per cent procaine, $1/50,000$ epinephrine	1
2 per cent procaine, $1/20,000$ epinephrine	2
$1/10,000$ epinephrine	2

veloped a falling out of hair at the tip of the tail. If these results are counted (and the occurred with a concentration of epinephrine as little as $1/100,000$), the number of rat's tails affected is increased by three.

The question might well arise as to why the rats did not show gangrene after injection with epinephrine. The probable answer to that, would be that there may be peculiarities in individual cases with respect to collateral circulation and as to the exact site of injection. However, the fact that the injection could cause gangrene in a concentration as low as $1/100,000$ is instructive.

Comment.—There has recently appeared an interesting article that probably has some bearing on the physiologic basis of the above experiment. Cammer and Griffith² have studied the effect of the intra-arterial injection of epinephrine on blood flow and respiratory exchange of the resting intact hind leg of the cat. When an appreciable concentration of epinephrine was injected intrarterially, blood flow and oxygen utilization were significantly decreased. This shows that cellular oxidation occurs at a lower level during the injection. Subcutaneous injection, without a doubt, has a similar but more prolonged disturbance on blood flow and oxygen utilization. With a lowered maintenance of cellular oxidation, tissue morbidity and tissue death can occur in an organ already weakened by infection and operation. In the quoted paper an almost exactly similar reduction of blood flow and oxygen utilization was produced by a low concentration of epinephrine as by a concentration two hundred times as great. This fact leaves open to doubt the wisdom of using epinephrine even in the weakest dilution in our anesthetic solutions for operation on organs having end arteries.

Summary

A case of gangrene of the toe following the use of a procaine-epinephrine solution for anesthesia is reported.

GANGRENE OF THE TOE, FOLLOWING LOCAL ANESTHESIA WITH PROCAINE-EPINEPHRINE SOLUTION

A Clinical and Experimental Study

LOUIS PELNER, M.D., Brooklyn

RECENTLY, there came to my attention a complication of a minor surgical operation which could have been avoided had the literature been widely known.

Gangrene of the finger or toe following injection of a procaine-epinephrine solution for local anesthesia preparatory to a minor surgical operation has not been stressed in the American literature, although the literature of the rest of the world is replete with the discussion of this complication.¹ That the offending agent is the epinephrine is fairly well agreed upon, since there is no such trouble found with the use of procaine solution alone.

The excellent textbook, *Minor Surgery*, by Christopher² quotes Baran's article in the *J.A.M.A.* and states:

"A very definite warning should be given in regard to the use of epinephrine in too great concentrations. Epinephrine, in what apparently is a very weak solution, is capable of producing necrosis of the tissues. I have not seen necrosis when the epinephrine has been 1:100,000, that is, one drop to a hundred drops of procaine. I believe, on the whole, however, that a safer rule would be 1:200,000, which would be 1 drop to 200 drops of the procaine solution. It is now possible to obtain commercial ampules of procaine of different strengths and amounts and with or without epinephrine or ephedrine."

These commercial preparations of procaine and epinephrine are put up by reputable firms and are so widely used that it is safe to say that there is not a physician in practice who does not at some time use them.

These ampules are made ready for use in concentrations of 1 and 2 per cent procaine and with $\frac{1}{20,000}$, $\frac{1}{50,000}$, and $\frac{1}{100,000}$ epinephrine. One large manufacturer issues a fine booklet on minor surgery where all of these preparations are suggested for use in the operations involving fingers and toes.

Extemporaneous solutions made by the nurse in the operating room and measured off in drops of epinephrine would probably contain much greater concentrations of epinephrine than even the great concentrations put up ready for use.

My contention, after reviewing the literature and after consultations with several surgeons who have had previous knowledge of the complications about to be described, is that epinephrine should not be used in operations involving the fingers and toes or should be used in minute concentrations, smaller than any recommended for this use by the manufacturer. Certain animal experiments to be described later suggest that it should not be used at all in certain structures having terminal circulations.

The advantages of epinephrine are that it allows for slower absorption of the local anesthetic and, thus, prolongs its action, as well as reduces the bleeding of the part. These are far outweighed by its tendency to produce local tissue death or morbidity.

Why are there not more cases described with this complication, which is certainly not so rare as the paucity of literature would make us believe? First, it is because gangrene is not always the outcome of a mild tissue injury. Many of us have experienced so-called "slow healing" finger infections postoperatively, where, after a time of impending necrosis, bountiful Nature comes to our aid after a short time. Second, one is not usually proud, for personal and legal reasons, to talk of one's failures.

Case Report

A. J., a healthy male adult, aged 30, in good physical condition, came in as an outpatient for the removal of an ingrown toenail on the big toe of the left foot. There were no other complaints. Local anesthesia with a procaine-epinephrine solution ampule (1 per cent procaine and $\frac{1}{50,000}$ epinephrine) was accomplished in the usual way—by subcutaneous injection around the base of the toe. Two cubic centimeters were used in the entire operation, and no tourniquet was used. Operation was accomplished without incident. A small rubber drain was inserted and a dressing was applied; no pain was felt.

About four hours later the patient was seen in extreme pain. There were several tremendous black and blue blebs over the entire toe, which were associated with intolerable pain. The patient was hospitalized. Sulfanilamide was given with the idea that this was a spread-

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

DEPARTMENTS OF MEDICINE AND PATHOLOGY, NEW YORK POST-GRADUATE
MEDICAL SCHOOL AND HOSPITAL, COLUMBIA UNIVERSITY

Date: January 20, 1942

Presiding: Dr. Irving S. Wright

History (Case J 60703)

DR. MAURICE BRUGER: This patient was a 59-year-old engineer formerly employed in a Chilean copper mine. He died four weeks after his first admission to the New York Post-Graduate Hospital. The chief complaints on admission were a persistently rapid pulse rate of six years' duration, dull occipital headaches of four months' duration, and vertigo associated with nausea and vomiting of ten days' duration. There was also diminution of vision of the left eye progressing to blindness during the preceding month.

The patient had been perfectly well until six years previously when he experienced an attack of diplopia which cleared spontaneously after three or four days. Shortly thereafter, he noted his pulse rate was constantly elevated. This was, however, not associated with dyspnea, orthopnea, precordial pain, or ankle edema. With the exception of the tachycardia the patient did well until the onset of the occipital headaches which were constant but relieved for four to five hours by salicylates. Shortly after the onset of the headaches, another attack of diplopia occurred. Two months previous to hospitalization he experienced a transient episode resembling a generalized convulsion without loss of consciousness. About a month before admission he complained of crampy, left-sided abdominal pain, which disappeared after the passage of flatus and feces. On the following day he noted impaired vision, which progressed until at the time of admission his left eye was totally blind. During a boat trip from Chile, he noted dizziness accompanied by nausea and vomiting when he changed the position of his head, and this persisted.

The patient was born in the United States but for the past twenty years had been a resident of Chile. During the previous year there had been a weight loss of about 20 pounds. There was no history of malaria or jaundice, and syphilis was denied. About twenty years ago the patient had a bout of undiagnosed hyperpyrexia and during the

same year passed a tapeworm in his stool.

On physical examination the patient was found to be a well-developed white man lying in bed with his head turned to the left. The left pupil was larger than the right and failed to react to light. It reacted consensually and to accommodation. There was limitation of the internal rotation of both eyes, with nystagmus more marked when looking to the right. Examination of the eyegrounds showed the disk in the left eye to be pale and indistinct in outline. There was a slight but definite left exophthalmos, which was interpreted by the ophthalmologist as being due to pressure behind the eyeball. Examination of the psychologic status revealed the patient to be intelligent and cooperative. The following positive neurologic findings were noted: Patient fell to the left during the Romberg test; the left toes were dragged in walking; there were increased tendon reflexes in the left arm and leg; moderate dysmetria in the finger to nose test was present as was a bilateral nystagmus (more marked to the right). Physical examination was otherwise essentially negative. Blood pressure was 122/82.

Laboratory Data.—Urinalysis: specific gravity, 1.030; negative for protein, sugar, cells, and casts. The blood count was normal; blood chemical studies were normal; the blood Wassermann reaction was negative. Spinal fluid examination revealed slightly xanthochromic fluid; no cells were found. The spinal fluid protein was 178.5 mg. per hundred cubic centimeters. The spinal fluid Wassermann was negative and the colloidal gold curve was 2,3,4,5,5,4,3,2,1,1,1,0. The electrocardiogram showed a nodal tachycardia with a rate of 142. An x-ray of the chest showed a small nodular mass 2 cm. in diameter in the posterior left costophrenic sinus, associated with moderate pleural thickening in this area. A film repeated eight days later showed the condition to be unchanged. An x-ray of the skull showed an increase in the soft tissue density of the left orbit and some clouding of the left ethmoid. Visualization of the optic foramina showed soft tissue tumefaction.

While in the hospital, flattening of the right

Some experimental evidence is adduced to show that it is the epinephrine in the mixture that caused the complication. An opinion is ventured that epinephrine should not be used in the anesthetic mixture in any concentration for operations on the fingers and toes.

MEDICAL EXPENSE FUND GOING TO TOWN

The present disruption of our social, political, and economic structures is presenting grave problems to medicine and will leave in its wake problems even graver—problems that should be solved now while there is yet time.

The agitation for governmental medicine, while temporarily shelved, will be renewed full force when the time arrives for getting the nation back on a peace footing at the close of the war. The medical profession, including the Nassau County Medical Society, is united in the feeling that the problem can best be solved through voluntary medical expense indemnity plans under medical supervision and that such a solution will be better for the patients as well as for the physicians than some scheme under political control.

The county society has approved the program of the Medical Expense Fund of New York. This organization is actually selling policies in Nassau County and to Nassau County residents employed elsewhere. We have a real, present opportunity to demonstrate that such a plan will work, but it can only work with the full cooperation of all the practitioners of the county. The

majority of our members have joined the plan as participating physicians; the others should do so at once.

The Franklin Square National Bank has pioneered in a sales program which is now being taken up by other banks throughout the metropolitan area. Under this plan the bank, without profit to itself or expense to subscribers, will enroll members in the fund and handle the remittance of premium. This makes it easy for anyone to secure the protection of a policy in the fund and will doubtless add many names to the list of Nassau County residents who will be coming to local doctors for medical care under the terms of their policies.

The Fund has recently announced a Family Policy, which is being well received and enables them to offer complete family coverage.

We urge the members of this society to: (1) become a participating physician, (2) take out a family policy for himself, (3) talk about the Fund to their patients, (4) handle all medical reports promptly so the Fund can keep its services rolling smoothly.—*Nassau Medical News*

FIRST-AID INSTRUCTION BY PHONOGRAPHS

At a meeting of the Society for Medical Jurisprudence held at The New York Academy of Medicine in February, the ninth anniversary of the Society for the Prevention of Asphyxial Death, Inc., was celebrated. The coordination of gases used therapeutically was discussed. It was urged that a department of pneumatology be established in every hospital for purposes of Civilian Defense. Such a department under the direction of the physician anesthetist would automatically afford facilities for asphyxia prevention outside, as well as inside, the hospital.

Dr. P. J. Flagg, director of the Society, announced that an effort was under way to meet the present dearth of first-aid instructors by supplying electric recordings free, at the earliest possible date, to at least 1,000 groups now preparing themselves in various parts of the country. It is extremely difficult, Dr. Flagg pointed

out, to secure overnight large numbers of people who are accustomed to think and to talk on their feet in public. On the other hand, such persons aided by electric transcriptions, providing a suitable standard background, can serve effectively as demonstrators, bringing home to the student the written word of the instruction booklet and the spoken word of the electric transcription. To make possible the project contemplated, the free distribution of 30,000 to 40,000 recordings, a fund of \$10,000 is needed. This fund will be utilized to provide the widest possible distribution at low cost. Contributions of any amount will be received and utilized as far as possible. Sets of eight recordings on the subject of resuscitation are now available. These sets retail at \$3.50 each and are to be had at your music store or at the office of the Secretary of S. P. A. D., 38 East 61st Street, New York.

would be worthwhile to read Bruns's and many other descriptions of similar cases.

Dr. Eidelsberg's Diagnoses

1. Cysticercus disease of the brain.
2. Bronchopneumonia.

Pathology:

DR. MAURICE N. RICHTER: With regard to the clinical diagnosis of brain tumor, it is worth noting that although lung tumors frequently metastasize to the brain, brain tumors do not metastasize to the lungs.

The principal lesions in this case are in the brain, the left optic nerve, and the lung.

The lesions in the brain are nodular, necrotic, friable areas in the left precentral gyrus, the left superior temporal gyrus, the right occipital lobe in the region of calcarine fissure, and the vermis, where a large mass replaces the cerebellar nuclei except for a portion of the left dentate nucleus. This mass reaches the tegmen of the fourth ventricle. Slight dilatation of the third ventricle and the aqueduct of Sylvius are found. The left optic nerve is markedly thickened and, at its thickest point, is 0.9 cm. in diameter.

The lesion in the lung is at the costophrenic margin of the left lung. It consists of a nodule, 4.3 by 3.5 by 2.5 cm., which is firm, grayish white, sharply defined from the surrounding lung tissue.

Microscopically, the lesions of the brain are unlike any recognized tumor. They consist of necrotic areas, with cellular infiltration associated with them, in the brain and the adjacent meninges. The cells are not always easily identified, but some are obviously lymphocytes and plasma cells. These cells bear no characteristic relation to the areas of necrosis, but in the neighboring brain tissue there is extensive perivascular infiltration with lymphocytes and plasma cells. No giant cells are found.

The optic nerve is involved in a similar necrotic and inflammatory process. The nerve bundles in the central part are necrotic. The cellular infiltration is similar to that in the cortical lesions.

The nodule in the lung is also necrotic. Here the process is more readily recognized. The central necrotic area has no recognizable cells, but the outlines of alveoli and blood vessels are still discernible. Elastic fibers of the vessel walls are readily demonstrable by suitable staining methods. Around the necrotic area is a dense wall of lymphocytes and

plasma cells. Giant cells are not encountered. This lesion we consider to be a gumma.

After a study of the several lesions in this case, we believe that all are on the same basis. While it is obvious that the brain lesions are inflammatory rather than neoplastic, it is not easy to prove beyond doubt that they are syphilitic. In this, the characteristic gummatous process in the lung is of considerable help. Numerous sections were stained by Levaditi's method for *Treponema pallidum* and by Steiner's modification, but no organisms could be demonstrated. However, we think a diagnosis of syphilis warranted on the basis of the histologic changes, in spite of the negative blood and spinal fluid Wassermann reactions. The other lesions in the case are only of minor importance.

Anatomic Diagnoses

Syphilis of brain (cerebral and cerebellar cortices).

Syphilis of optic nerve, left.

Syphilis of lung, left lower lobe.

Internal hydrocephalus.

Lobular pneumonia, right lower lobe and left lower lobe.

DR. EIDELSBURG: Undoubtedly this is an exceptional case. It emphasizes how difficult the diagnosis of syphilis may be clinically, if not also pathologically. The diagnosis of syphilis and gumma cerebri in the absence of history, positive serology, aortic disease, and so on, makes clinical reasoning feel its futility on such occasions. However, if it were impossible to arrive at such a conclusion clinically, it was also none too easy for the pathologist even when the lesions were in his grasp or on the slide.

DR. RICHTER: In the description of this case I have indicated the difficulty of proving the syphilitic nature of the process. In view of the discussion, a further statement is necessary. It is seldom that we are able to demonstrate organisms in gummas. The diagnosis is usually based on the morphology of the lesion, without demonstration of the inciting cause. It is possible for the lesions of *C. cellulosa* to simulate gummas. However, in this case the necrotic areas are not the result of degeneration of a parasitic cyst but of the tissues of the organs involved. As mentioned in connection with the lung lesion, the necrosis involves actual lung tissue, of which certain details can still be recognized. While we cannot prove beyond doubt that it is syphilis, we can be reasonably certain that it is not

side of the face was noted and the neurologic status continued to change. Bilateral Babinski reflexes appeared, the hyperreflexia on the left side increased, and the tongue deviated to the right. The patient gradually weakened and became semicomatose. On the twenty-second day of hospitalization, papilledema and hemorrhages in the superior temporal portion of the fundus of the left eye were noted. Bronchopneumonia developed and the patient expired.

Discussion

DR. JOSEPH EIDELSBURG: First, I want to state that this is an unusual syndrome. I do not know why, but for the fourth time at these conferences I have been given a neurologic problem. It emphasizes, however, that neurology and internal medicine cannot be divorced. The review of this case impressed me with the number and diversity of the signs and symptoms. I would, therefore, like to analyze and present it my own way.

When faced with such a multiplicity of neurologic findings, our first problem is to try to localize the lesion or the lesions. No one lesion could possibly give all the signs and symptoms enumerated in the history. Even an amateur neurologist like myself would know that the lesions must be multiple and disseminated.

Now let us group the following findings: a transient, recurrent diplopia, impaired vision leading to blindness of the left eye, inequality of the pupils, and an x-ray of the skull which showed a shadow in the orbit. If we take this group of symptoms and try to localize the lesion responsible for them, we may consider two locations: one, a lesion in the orbit possibly extending within the skull and, second, a lesion involving the optic nerve.

A second group of findings consists of occipital headache, vertigo, nausea, vomiting, nystagmus, a positive Romberg test, and dysmetria. This group of symptoms is typical of a lesion of the fourth ventricle or cerebellum and is also known under the name of Bruns's syndrome.

We have a third group of findings which we have not explained. These consist of a deviation of the tongue to the right and paralysis of the right side of the face. Also unexplained is a weakness on the left side of the body. These may possibly be explained by a lesion in the medulla or in the pons.

Now, although these three lesions include a multiplicity of signs, the tachycardia is still

unexplained. We are, however, close to the nucleus of the vagus nerve. We do not have any other signs to prove that a lesion exists here.

Having thus placed our lesions, the question is what one disease can produce these findings? I believe that in making a diagnosis, one should try to find the disease that covers all the symptoms and signs or, at least, the greater number of them. I have omitted the bronchopneumonia because I feel that this was not the primary cause of death. Are we dealing with a degenerative or neoplastic disease in this patient? Syphilis and tuberculosis are great imitators of many types of pathology. Could he not have had gummas in these various places? Against this is the fact that he had a negative Wasserman in the blood and spinal fluid. There was no history of a chancre and no signs of syphilitic aortitis. Can tuberculosis cause so complex a picture? We have no history or clinical findings of tuberculosis. I am inclined to feel that the diagnosis of tuberculosis may be excluded in this case because of the absence of cough and other confirmatory evidence of tuberculosis. Disseminated sclerosis can give some of these findings. It does not, however, explain the nodular pleural mass or the xanthochromic spinal fluid.

Now let us consider new growths. Because of the long duration and diversity of the findings, I think that we can rule out a brain tumor, either primary or secondary. The nodule in the lung does not resemble carcinoma.

At this point I should like to suggest another possible diagnosis—namely, cystic disease of the brain following cestode infection. This man had previously passed a tapeworm. He was employed as an engineer in a mine in Chile where sanitary conditions were probably inadequate. There are four types of cestodes that have to be considered: (1) *Taenia saginata*, which is a type that rarely gives rise to cystic disease of the brain; (2) *Bothriocephalus latum* which is rarely found in the brain; (3) *Taenia echinococcus*, which may be multiple and generally affects the liver in addition to the brain; (4) *Taenia solium*, contracted by eating contaminated pork that has not been well cooked. Following infection with this cestode, dissemination can occur to all parts of the body including the brain and lungs. When this disease invades the brain, it is known as *Cysticercus cellulosae*. This disease may adequately explain our findings and, if we had the time, it

Special Article

ORGANIZATION OF EMERGENCY MEDICAL SERVICE IN NEW YORK

GEORGE BAEHR, M.D., New York City

IT IS difficult to avoid repeating what I said yesterday on two occasions in this Academy of Medicine. Yesterday afternoon we had an audience of more than eight hundred persons crowded into Hosock Hall and another smaller audience in the evening. At that time I tried in half an hour to give a picture of the Emergency Medical Service organization and operation.

The Emergency Medical Service is directed by a Chief of Emergency Medical Service. In this city he is Dr. Edward Bernecker, general medical superintendent of hospitals, who is thoroughly familiar both with our voluntary and municipal hospitals. He was chosen because the Emergency Medical Service is organized within, or is related to, hospitals. In each borough a Borough Chief of Emergency Medical Service has been appointed by the Mayor. For this position he designated an outstanding physician who had the confidence of the medical profession—namely, the man who had been designated by the county medical society as chairman of its medical preparedness committee.

Throughout this state, Mr. Mailler, chairman of the Health Preparedness Committee of the State Defense Council, and Dr. John Bourke, executive director of that committee, have systematically recommended the chairman of the medical preparedness committee of each county medical society as the local chief of emergency medical service. This was done because we found that the county medical societies quite uniformly had selected the best men in their councils, men who were interested, thoroughly interested, and had a capacity for leadership.

That man plays an important role, because he must see that the hospitals are operating along the lines which have been outlined in Medical Division *Bulletins* Nos. 1 and 2, with which you are familiar. They have been distributed to all hospital chiefs of staff and to directors of hospitals, as well as to the state and county medical societies, and have been reprinted in the *Journal of the American Medi-*

cal Association. After December 8, the day after the Pearl Harbor attack, the A.M.A. reprinted both bulletins and redistributed them to every hospital in the United States of more than twenty-five beds. There is, therefore, no reason why everyone should not now be thoroughly familiar with the organization and the operation of the Emergency Medical Service.

Under this service, the care of civilian casualties will be handled by Emergency Medical Field Units which are organized in hospitals or, if they are organized extramurally, they should be related to hospitals. Emergency Field Units created out of the doctors and nurses practicing in the community cannot be mobilized promptly in the event of sudden and unheralded bombing. The field units related to hospitals are available for immediate service at any time of the day or night.

Emergency Medical Field Units have now been organized in eighty hospitals in this city through the efforts of your chiefs of Emergency Medical Service and Dr. Bernecker. Each is subdivided into squads of two to four doctors, an equal number of nurses, and about double that number of nursing auxiliaries. In large hospitals a number of squads will always be on call day or night. The Medical Field Units do not move when the alert is sounded; they do not move when the air-raid warning is given. They prepare for action and move out of the hospital only on a direct call of the control center.

In this city a main control center controls the operation of seven district control centers. The person in command of the main control center is Deputy Chief Inspector John J. O'Connell. His field director is Inspector Wallander, who has been in England as an observer, having been sent over by the Mayor to study this problem.

In each district control center the commander is assisted by a staff of technical experts for each of the technical fields who will assemble as soon as the alert is sounded. The fire department is represented, as well as the various public utilities and each branch of the city government which participates in

Read at The New York Academy of Medicine, December 22, 1941.

tuberculosis or cysticercus disease. I think the possibility of some other condition is rather small.

DR. WRIGHT: If we accept the pathologic diagnosis as final (and in this case it may not be without some doubt) we are reminded of the conclusion with which Delafield often terminated his course: "Above all, gentle-

men, remember that the common diseases are the common ones."

Editorial Committee

J. SCOTT BUTTERWORTH, M.D.

MAURICE R. CHASSIN, M.D.

N. Y. ADULT EDUCATION COUNCIL

More than 2,000 organizations offer educational and recreational opportunities to the 4,500,000 adults in New York City. The New York Adult Education Council was founded in 1933 to centralize information concerning the thousands of activities offered to adults, to make that information available and useful, to help the producers of education better understand the educational needs of the public, and by conferences and consultation to bring about the co-operation among organizations that would result in better service to adults in pursuit of education.

During these eight years 75,000 adults have been given information concerning both free and fee offerings. This means that the Council file of more than 20,000 activities must be kept up to date at all times. Through trained interviewers the Council has set a high standard for this service, for its specializes in personalized help. Whether the inquirer is seeking vocational training, sports, a hobby, social activities, forums, or lectures, his personal need and his ultimate purpose are carefully considered.

The Council is located at 254 Fourth Avenue, New York. Telephone: ALgonquin 4-7150.

SYMPOSIA—DENTAL CARIES

To foster a better understanding of the dental health problem among physicians and dentists, the Maternity, Infancy and Child Hygiene Division of the New York State Department of Health, in conjunction with the State Medical Society and District Dental Societies, is sponsoring a series of three symposia on "The Control of Dental Caries" to be given in Rochester on March 31, Binghamton on April 1, and Albany on April 2.

Invitations to participate in these symposia are being extended to outstanding national authorities. It is planned to center the discussion about the three major influences which today are attracting the most thought in connection with dental caries; namely, the role of nutrition, of oral flora, and of the fluoride content of drinking water.

It is believed that these meetings should not only prove of wide interest, but that the discussion is particularly timely because of the recognition of the importance of dental caries, brought about by the findings of the Selective Service examinations.

More detailed announcements, giving the final program, the time and place of meetings, will be made to the members of the medical and dental professions in the near future.

"DEMOCRACY CARES"

"It was exactly ten years ago this month: The unmet problem of mass want was of such disheartening magnitude as to appear insoluble." These, and the following, are the words of David C. Adie, commissioner, New York State Department of Social Welfare, in the Foreword to *Democracy Cares—The Story Behind Public Assistance in New York State*. Yet, in those bleak days of November, 1931, New York became the first state in the nation to meet that challenge. And year after year since, New York State has shown the way to the prevention of need that stems from unemployment, a problem which—we now know—renews itself every day.

For years you have seen community chest posters which bear the legend: Suppose Nobody Cared!

Democracy cares!

This report shows why and how and with what results. It tells the story of Public Assistance.

It is an important story, since it concerns human beings. It is a tremendous story, because it describes the mass drama of powerful forces that

belittle and damage human beings. It is a hopeful story, for it shows we are learning to help people who need help. It is a timely story, because it identifies forces which threaten democracy from within.

There is added point in presenting this booklet today. Democracy is today taking inventory of its resources for defense. Home defense. Public Assistance is, always has been, home defense—insurance of our democratic way of life. It has ended the want and distress of millions of American men, women, and children—the social chaos upon which foreign ideologies feed and grow. Insecurity in Europe helped to produce totalitarianism—all brands. In America it produced—Public Assistance, a historic expression of democracy. The care of all is the concern of all, in the United States.

To the 13,500,000 Americans of New York State and their freely elected representatives who again played a pioneer part in making democracy work, this booklet is dedicated. In its pages is the story of what they did, how they did it, and why.

splint if it is necessary before the patient is moved.

It is the experience of the British, and previously it was the experience in Spain, that air-raid casualties are of two types: the seriously injured and apt to die and the slightly injured. Of the seriously injured about 50 per cent are killed outright or die shortly after the injury. Hence, the need for medical judgment and experience at the first-aid post if those who are still alive are to be saved. The mildly injured are walking cases who do not require hospitalization for the most part, but some place must be provided for them where they can receive medical and first-aid care and where they then can rest. They must not be permitted to clutter up the first-aid post or the admitting rooms of the hospitals. For them, casualty stations have been provided which are reasonably convenient in location and are equipped with beds, cots, blankets, and canteen service. The minor casualties and the people suffering from nervous shock and hysteria are directed to the casualty stations where there are doctors, nurses, and nurses' aides capable of taking care of them. Here they can rest and be observed long enough until it is considered safe to permit them to return to their homes or to a temporary shelter.

This gives you a brief picture of the operation of the Emergency Medical Field Units. They have been organized in this city in eighty hospitals and, I am told, have a personnel of 2,148.

The training and organization of a disciplined corps of nurses' aides is most important for service in casualty stations and first-aid posts. In Great Britain there are four nurses' aides to every nurse in the first-aid posts. That may be necessary here because the nursing services of our hospitals are badly depleted and we shall not be able to spare many nurses from our hospitals if there are large numbers of casualties. This also applies to hospital doctors.

We have organized our Emergency Field Units primarily in hospitals because we must be ready day or night for the unexpected attack. The interns and residents have, therefore, been organized under the leadership of a surgical intern or an assistant surgical resident. We advise that other surgical interns and residents be retained in the hospital for service in the operating rooms. The staff of the medical, the pediatric, the neurologic, and other nonsurgical services can be spared from the hospital at least temporarily.

But, if we should have continuous bombing for any length of time—we don't expect to have it, but we must be prepared—they must be drawn back for service in the hospital. It will then be up to the medical profession of the city to man the first-aid posts and casualty stations. The doctors of the neighborhood will take their periods of duty in the casualty stations and first-aid posts for as many hours a day as they may be called upon to serve. But we do not need them now, and it is as yet unnecessary in this area to organize them into units. The doctors in the hospital should be drilled. Hospital drills and field drills should be held every week. But if we are ever in serious trouble, all doctors in the community will be needed.

We shall also need them for what the British call the "incident" doctor who is important. He appears after an incident and reports for duty to the nearest casualty station both to assist in its work and to establish public morale. On the day after an incident, he gets a list of the casualties and visits them *not only to check on their injuries but also to make them appreciate the fact that their government is interested in them and wants them to be cared for.* After the first record is made at the casualty station, they may get their service from a private physician; if they cannot afford a private physician, they can go to the casualty station or to a hospital clinic.

People injured in air raids may ultimately have to be compensated. No provision has yet been made by the Federal Government for this purpose, but in Great Britain they have had to do it. As there is a possibility of future compensation for air-raid casualties, a record must be kept of all casualties in the first-aid posts, at the casualty stations, and in the hospitals on forms which will be supplied from the Office of Civilian Defense. Record books are already available for issue.

The city must organize a Casualty Information Service so that people who have been bombed out of their homes may locate their relatives and friends. The deputy chief of Emergency Medical Service at the district control center must know the number of casualties and of deaths and the total figures must be recorded to the main control center. A unified transport service must be available under the central control of a transport officer. A mortuary service must also be organized.

There will be need for many doctors. We

the air-raid protection service of the city. The Medical Protective Service will be represented by a deputy chief of the Emergency Medical Service. A medical deputy will also be assigned to each district control center with assistants who can relieve him at periods of the day.

I understand that the medical profession of the city is anxious to learn how doctors are going to be used in civilian defense. If they will be patient they will all be drawn into service in various ways.

At each district control center there is need for at least three doctors who can alternate in periods of service during the day whenever the control center is operating. Although they may continue to practice medicine and do their work in hospitals, they must be prepared to give four hours of service a day if the need should arise. They must be trained by the Chief of Emergency Medical Service so that they are thoroughly familiar with all the medical facilities in their district and can truly serve as the medical adjutant to the commander of district control centers. They must know the available facilities not only of the hospitals in the district but also those assigned to the district. They must also know how many medical squads are available day or night in each of the hospitals that are to man the casualty stations and the first-aid posts. As we get into action they must have a daily census of vacant hospital beds that are available to receive casualties.

It has been determined by British experience that a fairly large hospital cannot care for and operate upon more than fifty major casualties in a day, and many of our hospitals cannot handle that many. After a hospital has received almost its full quota, it notifies the control center and, thereafter, the casualty stations and first-aid posts are directed to send casualties into other more remote hospitals assigned by the main control center to the district.

A peacetime disaster usually occurs at a single site, and the person in control, the Police Commissioner, can mobilize all the fire fighting and the medical forces of the city and, if necessary, throw them all into the breach at that one point without depriving the rest of the city of essential services. But in war, when incendiary bombs or explosives are raining upon many centers throughout the city, it is necessary to work in districts in which all the facilities of that area—the medical, the fire fighting, the utilities, and all

other essential services—are under the control of the commander of the district.

When the medical squads of the hospitals move out at a command from the district commander or his medical adjutant, they proceed to specifically designated casualty stations. A spot map of the city has been made by the Chief of Emergency Medical Service, and in each of the districts there are indicated not only the hospitals and how many squads are available day and night in each one but also the sites of the casualty stations. These are clinics of hospitals and health services, district health centers, health department substations, baby health clinics, and a variety of structures that lend themselves to this purpose.

These casualty stations are numbered and the squads are directed to man one or more stations. They are equipped as described in Medical Division *Bulletin No. 2*, not for major surgery but for first-aid work.

At the casualty station one or more teams of a doctor, a nurse, and several nursing auxiliaries with their equipment may be split off and dispatched forward to establish advanced first-aid posts close up to the site of the disaster. Surgery is not done either at a casualty station or at a first-aid post if it can be avoided; it is done at the hospital to which the severe casualties must be transported by ambulance as rapidly as possible.

The first-aid post receives the severe casualties as they are extricated from the demolished building by rescue squads. The latter are auxiliaries of the fire department who have been trained in fire fighting and in demolition work and are equipped with demolition tools. They are also trained in first aid, but that is only an incidental service if no physician or first-aid post is available, their primary job being to get the injured people out of the ruins. They can then hand them over to the first-aid post, and that usually requires stretcher transportation. The rescue squads are, therefore, assisted by teams of trained volunteers called by the British "First Aid Parties"; we prefer to call them "stretcher teams" for a good reason. Their chief problem is to deliver the injured to the first-aid post. In this country, certainly in our larger cities, the first-aid work upon the seriously injured is to be done under the direction of a physician. The doctor at the first-aid post is most important, for he must decide priority in the prompt transportation of the seriously injured to the hospital. He must do whatever is essential to prevent shock. He must apply a traction

Service or from their private physicians."

If physicians attempt to set up organizations without relationship to the common plan it will impede and not help the Chief of Emer-

gency Medical Service. It will serve to confuse the public and the medical profession.*

* In view of the information on the Procurement and Assignment Service published on page 558, the section of Dr. Baehr's talk covering that subject has been deleted.—Editor.

POPULATION PROBLEMS IN JAPAN

Now that war is upon us, we can profit from more knowledge regarding our adversaries, says the *Statistical Bulletin* of the Metropolitan Life Insurance Company. What, for example, are some of the principal characteristics of the population of Japan?

On a relatively barren, mountainous group of islands, not quite equal to California in area, Japan sustains the life of more than 73,000,000 persons. The population density is 490 per square mile, more than 10 times that of the United States. This in itself does not necessarily involve any great hardship; other nations which make no great complaint of overpopulation live under conditions of much greater density—as, for 700 inhabitants per sq with 706. These are h : ions which largely import their foodstuffs while exporting manufactured goods.

The soil of Japan does not produce enough food to maintain the life and health of its people on a high standard. Actually, more than 10 per cent of the rice consumed in Japan is imported. Industrial organization has made remarkable strides in past decades, but it is far from sufficient to raise the standard of living to the levels we take for granted for ourselves. Encouragement by the government to relieve the population pressure by emigration to Japanese colonies has met with little success. Further development of Japan's industries would seem to be the first and natural remedy for her population problem, though she is seriously handicapped by lack of raw materials, in particular coal, oil, and iron.

To appreciate present conditions in Japan, it is necessary to make a survey of the recent past. In one respect Japan has differed fundamentally from our Western civilized communities. We, in the United States, have long been accustomed to a gradual diminution in the rate of increase of our population. At the beginning of the nineteenth century this rate was about 30 per 1,000 per annum, and this has declined in an essentially regular and orderly manner to about 7 per 1,000 per annum today. We see nothing disturbing in this gradual moderation in our rate of increase. Indeed, quite on the contrary, it would have been embarrassing had the original rate continued to the present. But, until 1935, the Japanese

authorities had been accustomed to an actual rise in the rate of increase of their population. In the course of the five-year period 1930 to 1935, the growth of the population was 7.5 per cent—that is, at a rate of 1.5 per cent per annum; then, in the next period, 1935 to 1940, this rate was reduced to 5.6 per cent, a rate of 1.1 per cent per annum.

This situation . . . inspired the formulation of a plan approved by the Japanese Cabinet in January, 1941. This plan aims at giving Japan a population of 100,000,000 by 1960, and frankly purposes to outrival other nations in rate of natural increase. It is modeled much on the lines of the German and Italian measures established for similar purposes and proposes various forms of subsidies to large families, with some degree of penalization of small families and unmarried persons. To us this solicitude must seem somewhat exaggerated when we reflect, for example, that even today Japan with its 73,000,000 inhabitants annually has nearly 2,000,000 births, not far below our own figure of about 2,250,000 millions in our population of 132,000,000.

In its mortality Japan lags materially behind us. The death rate in Japan, according to recent figures, is 17.4 per 1,000, as against a rate of approximately 10 or 11 in our own experience [peacetime figures]. The fact is that recent conditions in Japan correspond to conditions here about 40 years ago Whereas our death rate from tuberculosis today is fortunately reduced to 45 per 100,000, that of Japan in 1937 was 204, a figure closely resembling ours for 1900—namely 196

The age distribution is itself a matter of outstanding interest today on account of its relation to the availability of men of military age. The proportion of men in the age group of 20 to 44 in Japan, according to the latest data available which relate to the census of 1935, is 34 per cent, corresponding to a total of 11,000,000. In our own population, the contingent of men of these ages constitutes 38.5 per cent, or a total of 25,000,000 There certainly cannot be much sympathy for a program that offers bonuses and all kinds of bribes to the average family to breed more freely, while on the other hand it claims that excess population is the justification for its territorial robberies.

doctors are ready and far better prepared I think than any other branch of the protective services of this city or any other city.

All doctors want to do something and they want to do it right away. That is a laudable impulse. So do druggists and dentists and almost everybody else. All the doctors and the dentists cannot be put to work until we are ready for them.

The American Pharmaceutical Association came to us some time ago and said: "What can the druggists do in civilian defense?" I laid out definite recommendations, but they were not at first happy about it. They wanted to do something more important. They felt that the first-aid post should be in drugstores where all the necessary supplies, medical and surgical, are immediately available. It did not require much argument to convince them that a pharmacy is one of the worst places for a first-aid post because of the amount of glass which constitutes one of the greatest hazards and the limitation in floor space. The fact that they have a few supplies available is not nearly so important as these other two considerations. Such supplies should be ready for purchase by people who want to replenish their first-aid kits. Some pharmacists were not satisfied; they went to state defense councils and to local defense councils and, finally, got to the sympathetic ear of one Director of Civilian Defense who heard their story. Not knowing its implications and being a good fellow, he said: "Sure, you can all be part of Civilian Defense. You can have a sign in your window and call yourself an emergency first-aid station."

That could not be permitted, for it would mean to the public that in the event of an air-raid casualty, they were to go to the druggist for treatment, rather than to the first-aid posts and casualty stations. These signs in the windows of the druggists had to be eliminated.

I called in the American Pharmaceutical Association and explained our difficulty. At our request, the American Pharmaceutical Association and the State Pharmaceutical Associations have gone down the line and have stopped this movement. We have also issued an official statement on the subject.

This is Medical Division Memorandum No. 7 sent out under date of December 15, 1941, which reads as follows:

"Large amounts of glass and space limita-

tions make pharmacies unsuitable sites for casualty stations and first-aid posts.

"Pharmacies are readily accessible in every community, are open during the greater part of the day and evening, and are visited frequently by members of the community. They are admirable sites for the dissemination of information.

"The stock of drugs, medicines, surgical, and sickroom supplies available for purchase in every pharmacy should be kept constantly replenished.

"What each pharmacist should do:

"1. Register with the Chief of Emergency Medical Service in this community, indicating the supplies he has available.

"2. If he has a delivery truck available for emergency transport, register it with the transport office of the local defense corps.

"3. Register his pharmacy with his air-raid warden, indicating the telephone and refuge facilities he has available.

"4. Place his services at the disposal of the local defense council for distributing hand bills, displaying placards, and other information on Civilian Defense.

"5. Inform himself of the organization, location, and character of protection facilities in his neighborhood so that he can direct citizens to shelter, wardens' posts, casualty stations, and first-aid posts.

"6. Review and extend his own training in first aid and prepare himself to instruct others in his employ.

"7. Large pharmacies should establish a first-aid detachment among their employees which can be immediately available as a stretcher team to assist the rescue squads in the extrication of casualties from demolished buildings and transport them to the first-aid posts of the Emergency Medical Service. For this purpose, it is advisable that pharmacies be equipped with a stretcher and with first-aid supplies.

"8. It is important that pharmacies avoid the use of any Civilian Defense designation which would tend to confuse the public concerning the location of casualty stations and first-aid posts of the Emergency Medical Service. Injured persons should obtain care at official stations of the Emergency Medical

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York will henceforth be published in this section of the JOURNAL. Members of the committee are Oliver W. H. Mitchell, M.D., chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

Treatment of Common Diseases

A course on the treatment of common diseases has been arranged by Dr. Clayton W. Greene, Buffalo University College of Medicine, Buffalo, New York, for the *Tioga County Medical Society*, Thursday evenings, 6:30 p.m., alternately Jenkins Inn, Waverly, New York, and Green Lantern Inn, Owego, New York.

March 19.—Treatment of Epigastric Distress Following Meals.

A. H. Aaron, M.D., professor of clinical medicine, Buffalo University College of Medicine.

March 26.—Practical Application of Hormonal Therapy.

Ivan Hekimian, M.D., assistant professor of medicine, Buffalo University College of Medicine.

April 2.—Treatment of Low Back Pain.

Frank N. Potts, M.D., associate professor of orthopaedic surgery, Buffalo University College of Medicine.

April 9.—Treatment of Common Skin Lesions.

Earl D. Osborne, M.D., professor of dermatology and syphilology, Buffalo University College of Medicine.

April 16.—What Do We Know About Vitamins.

David K. Miller, M.D., professor of medicine, Buffalo University College of Medicine.

Arteriosclerosis and Ageing

A course on arteriosclerosis and ageing, arranged by Dr. J. Murray Steele, New York University College of Medicine, New York City, for the *Jefferson County Medical Society*, is to be held on Thursday evenings at 6:30 p.m. at the Black River Valley Club in Watertown, New York.

April 9.—Clinical Interpretation of Modern Physiological Concepts.

J. Murray Steele, M.D., associate professor of medicine, New York University College of Medicine.

April 16.—Pathological Aspects.

Sigmund L. Wilens, M.D., assistant professor of pathology, New York University College of Medicine.

April 23.—Neuropsychiatric Aspects; Diagnosis and Treatment.

S. B. Wortis, M.D., associate professor of neurology, New York University College of Medicine.

May 14.—Renal and Cardiac Aspects; Diagnosis and Treatment.

William Goldring, M.D., associate professor of medicine, New York University College of Medicine.

May 21.—Peripheral Vascular Aspects; Diagnosis and Treatment.

Irving S. Wright, M.D., professor of clinical medicine, College of Physicians and Surgeons, Columbia University, New York City.

DIABETES ASSOCIATION TO MEET

The New York Diabetes Association, Inc., will hold a clinical meeting on Thursday, March 26 at 8:30 p.m. at The New York Academy of Medicine.

Dr. Beverly Chew Smith, chairman, Committee on Surgery will preside. "Reduction in Mortality Due to Gangrene in the Diabetic" is the subject of the symposium which is as follows: "By Prevention," Dr. Frederick W. Williams; "By Use of Sulfonamide Drugs," Dr. Samuel Standard; "By Use of Cold as an Anesthetic Agent for Amputations," Dr. Lyman W. Crossman; "By Amputations Below the Knee," Dr. Beverly C. Smith.

Each paper is limited to ten minutes. After the papers, a panel discussion with questions from the audience will be conducted by the speakers and the following discussors: Drs. Frederick M. Allen, James R. Lisa, Herman O. Mosenthal, Thomas J. O'Kane, and Samuel Silbert.

All physicians and medical students are cordially invited to attend this meeting.

PUT IT IN WRITING . . .

. . . says Edward Hall, M.D., in *Medical Economics*. He continues:

"When I began practice, I naively underestimated the forgetfulness of patients. But I've learned.

"I can remember giving one patient several verbal instructions for the care of her sore throat. I told her to take a prescribed capsule every two hours, to use a hot saline gargle every hour, to follow a liquid diet, to take a laxative, and so on.

"Next day she reported that she had carried out my orders faithfully and felt so much better. She had gargled with cold water every three hours, had taken bicarbonate of soda, and had forgotten the rest. Fortunately, this patient *did* feel better. But one or two other cases did not fare so well.

"I now make it a rule never to give more than two verbal orders in cases where an exact treatment routine is vital. Though it takes me a minute or so longer, I find it much better policy to hand the patient specific, written instructions for the management of his illness."

Medical Preparedness

It was announced in the March 1 issue that the official information from the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, published in the J.A.M.A., February 21, 1942, would be reprinted in this issue of the JOURNAL. In its place we are substituting a recent communication from the New York State Procurement and Assignment Service which gives the information in a more concise form.—Editor

Procurement and Assignment Service

IN EACH Corps Area there is appointed, by order of the Secretary of War, a Procurement and Assignment Service to "procure and assign" doctors, dentists, and veterinarians to the Army, the Navy, the Public Health Department, the Civilian Defense, Industrial and other government agencies, and the services necessary for the civil populations.

- I (a) All physicians under 36 years of age desiring *immediate commissions* should write now to the Procurement and Assignment Service, 601 Pennsylvania Avenue, Washington, D. C.
- (b) This will constitute *their application*, and those who qualify will receive proper application forms with a view of commission in the Army or the Navy.
- II All physicians *over* 36 years should *await* the receipt of the new enrollment forms.
- III Within the next few weeks the enrollment forms will come to you in the mail from Washington.
- IV Make out your form *promptly*. By authority of the President of the United States, the Procurement and Assignment Service receives requests for personnel from the following agencies:

United States Army Medical Corps
United States Navy Medical Corps
United States Public Health Service
United States Veterans Administration
United States Civil Service Agencies
St. Elizabeth's Hospital (Washington, D. C.), resident staff and interns only
United States Indian Service
Panama Canal Service
Full-Time Service in Office of Civilian Defense

When you fill out the blank forms, you may indicate your preference.

- V You may not hear from the Procurement and Assignment Service for some months. You will only hear from the P. and A. Service in Washington when any of the above listed agencies requisition assigning you to duty such as *you* can give.

Military Service. All individual inquiries for information concerning a commission should be addressed to the Procurement and Assignment

Service, 601 Pennsylvania Avenue, Washington, D. C. Then the necessary papers will be sent to you.

Selective Service. Any physician who happens to be called before his local board should show the board *that he has already enrolled* with the Procurement and Assignment Service. If he is classified in 1A, he should ascertain from his local board whether or not an inquiry has been addressed to the Chairman of the Second Corps Area Procurement and Assignment Service to get data as to the status of the registrant—whether in the opinion of this Committee the registrant is a *necessary man* in his civilian capacity, and whether or not *he has enrolled* with the Procurement and Assignment Service for governmental service. In the rare instances where local boards *have failed* to make such an inquiry, the registrant should contact the *Government Appeal Agent* at the local board and *complete the necessary papers* for an appeal.

There are no blanket deferments possible under the Selective Service Law; each individual registrant's status is individually determined.

The absolute necessity of enrolling yourself with the Procurement and Assignment Service thus becomes obvious. Every effort will be made by the State Procurement and Assignment Service to obtain a temporary deferment of those physicians whose commissions are under way.

No efforts will be made by the State Procurement and Assignment Service to obtain temporary deferments for any physicians who either fail to enroll with the service or who make efforts in any way whatsoever to avoid serving his country in this time of War.

While it does not specifically concern physicians, identical procedures are in force for dentists and for veterinary surgeons. These professional groups will get all necessary information from their representatives on the State Committee.

The entire procedure, personal authority, and activity are outlined in the J.A.M.A. 118: No. 8, 625 (Feb. 21) 1942.

SAMUEL J. KOPETZKY, M.D., *Chairman*
New York State Procurement & Assignment Service

292 Madison Avenue, New York City

Buy U. S. Defense Bonds and Stamps

bert H. Baucus, chairman, Committee on Industrial Health, Medical Society of the State of New York. Dr. Harvey P. Hoffman, president, Medical Society of the County of Erie, was chairman.

"Industrial Pulmonary Diseases," by Dr. Leroy U. Gardner, director of Saranac Laboratory, Saranac Lake, New York; discussion by Drs. Donald R. McKay and J. Herbert Donnelly.

"Techniques of Physical Examinations in Industry and Medical Standards for Rejection," by Dr. B. L. Vosburgh, medical director, General Electric Company, Schenectady, New York; discussion by Drs. George G. Martin and Donald C. O'Connor.

"Systemic Effects of Various Substances Commonly Used in Industry," by Dr. J. H. Sterner, director, Laboratory of Industrial Medicine, Eastman Kodak Company, Rochester, New York; discussion by Drs. Francis D. Leopold and John P. Boroszewski.

"Traumatic Surgery with Emphasis on the Treatment of Wounds and Shock," by Dr. Henry H. Ritter, director, Traumatic Surgery Service, Post-Graduate Medical School and Hospital, Columbia University; discussion by Drs. Albert A. Gartner and John C. Brady.

General discussion and questions followed.

The University of Buffalo Medical Alumni Association will hold its Eighth Annual Spring Clinical Day on Saturday, March 28 at 9:30 a.m. at the Hotel Statler in Buffalo.

The following men will appear on the program and speak on topics of general interest: Dr. P. S. Hench, the Mayo Clinic; Dr. Carl Badgley, University of Michigan; Dr. Maxwell Wintrobe, Johns Hopkins Hospital; Dr. H. T. Hyman, New York City; Dr. Frank Lahey, president of the American Medical Association.

Franklin County

On February 11 the Saranac Lake Medical Society heard Dr. John N. Hayes, medical director of the Gabriels Sanatorium, talk on "Conditions Simulating Pulmonary Tuberculosis."

Genesee County

A scientific meeting to which all physicians and nurses were invited was held under the sponsorship of the county society and the Emergency Medical Service of Genesee County at the United States Veterans' Facility in Batavia on March 5.

Dr. Peter J. Di Natale, secretary of the county society, is head of the Emergency Medical Service. Five speakers, each giving a ten-minute talk on the care of war wounds and Civilian Defense protection, made up the program.

A business meeting of the county society was held at the Batavia Club on February 26.

Jefferson County

Preceding the February meeting held at the Black River Valley Club in Watertown on the tenth, dinner was served at six-thirty. The program included the second symposium on sulfonamide therapy. Dr. Allister M. McLellan, Cornell Medical School, New York City, and Dr.

Edward C. Hughes, Syracuse University College of Medicine, led the discussion.

The third session was held on February 24. All speakers and their subjects were published in the Postgraduate Medical Education Section of the JOURNAL on February 15.

See page 557 for postgraduate lectures.

Kings County

Dr. William C. Meagher was felicitated on his recent election to the presidency of the county society by more than one hundred persons on February 11 at the annual dinner of the Alumni Association of St. Catherine's Hospital in the Hotel Bossert, Brooklyn.

Associated with the hospital since he interned there in 1917, Dr. Meagher was praised by United States Attorney Harold M. Kennedy; City Court Justice Edward L. Kelly; Henry Mannix, president of the hospital's board of managers; Dr. Charles A. Gordon, chairman of the Brooklyn Chapter, American College of Surgeons; and Dr. Thurston S. Welton, editor of the *American Journal of Surgery*.

Dr. William T. Carrington, president of the society, presented him with a gold watch. Others at the dais were the Rev. Paul Faustmann, associate diocesan director of Catholic Hospitals, and Dr. John J. Gainey, president-elect of the county society.

Dr. John A. McCabe, chairman of the arrangements committee, was assisted by Dr. George F. Cunningham, Dr. Leslie H. Tisdall, Dr. Dominick F. Rossi, Dr. Raphael J. Di Napoli, and Dr. Vincent Anello.

The March 6 meeting of the East New York Medical Society was as follows:

A case report, "Combined Hyperthyroidism and Adrenal Cortical Insufficiency," was presented by Drs. Leo Gitman, Morris Ant, and Mendel Jacobi.

The paper of the evening was "The Recognition and Treatment of Anemia," by Dr. Paul Reznikoff.

Monroe County

At a joint meeting of the county society, the Rochester Academy of Medicine, and the University of Rochester Medical School on February 22, Dr. Albert D. Kaiser spoke on "Know Your Child's Heart."

Nassau County

At the joint meeting of the county society and the woman's auxiliary held on February 24 at the Cathedral House, Garden City, Dr. Richard M. Brickner spoke on "Mental Hygiene and Its Uses During War." Dr. Brickner is on the staff of the Neurological Institute in New York City.

The *Nassau Medical News* for February carries an article entitled "What to Do in an Air Raid." On the subject of first aid, the article includes this striking sentence: "The mortality rate [in England] in air-raid casualties is in direct proportion to the amount of work done on the victims in the field; the more you do before the patient gets to the hospital, the larger the percentage of cases which will result in death."

Medical News

State Health Program a Success

NEW York State's new community health program, now in operation for a year under auspices of the State Welfare Department, has proved workable and beneficial in nearly every instance, sixty commissioners and medical directors of city or county divisions agreed at a report meeting held in Albany on February 26.

Deputy Commissioner Lee C. Dowling stated that the program, already set up in twenty-nine communities, would be retained and expanded. With the medical directors, the commissioners will work out jointly the minor changes advocated after a year of experiment. Dr. Christopher Wood represented the State Medical Society.

County News

Albany County

Dr. Will Cook Spain of the New York Post-Graduate Medical School and Hospital was guest speaker at the February meeting of the county society on February 25. The meeting was in the auditorium of the College of Pharmacy. His subject was "The Treatment of Bronchial Asthma," and Dr. Harold P. McGan led a discussion after the talk.

Bronx County

On February 18 the county society held its regular meeting at Burnside Manor. The scientific program consisted of an address by Dr. Leonard Greenberg, director of Industrial Medicine, Department of Labor, whose talk was entitled "The Administrative and Preventive Aspects of Industrial Hygiene." Dr. May R. Mayers of the Division of Industrial Hygiene, Department of Labor, spoke on "Clinical Problems in the Diagnosis of Occupational Diseases."

Chemung County

The regular meeting of the county society was held on January 28, 1942, at the Arnot-Ogden Memorial Hospital, Elmira, and was called to order by the president, Dr. Leon Hamilton.

Dr. John Burke, Jr., reporting for the Post-Graduate Education Committee, stated that arrangements were being made for a one-day meeting. Men qualified in their special fields will come to Elmira to discuss the handling of conditions that might arise from wartime emergencies. A day early in April will be selected for this meeting.

Dr. Ross Loop, reporting for the Medical Preparedness Committee, stated that his committee had organized the county society into eight squads consisting of four men each—sixteen men assigned to each hospital, making a total of thirty-two men. Three or four additional men were listed as reserves for each hospital. Each squad is assigned to one particular sector of the county. In case an emergency arises the duty of the squad is to render first aid and then to classify the patient and decide whether or not hospitalization is necessary. Four nurses are to be assigned to each squad. Following his report, Dr. Loop introduced the speaker of the evening, Mr. Edgar Austin, deputy chief of Civilian Defense of Chemung County.

Mr. Austin acquainted the society with the fact that the civilian population of the county is being efficiently organized to cope with all matters of Civilian Defense. He also stated that

rescue squads were to be assigned to each squad of doctors and that auxiliary ambulances such as station wagons, etc., were being organized and registered. He mentioned the splendid response to the request for people to take the first-aid courses and the excellent job the Red Cross was doing in teaching these courses.

Following his talk, Mr. Austin showed British movies including scenes of the evacuation of Dunkerque, methods of extinguishing incendiary bombs, the British fire-warden system and the British coastal anti-aircraft corps in action.—*H. L. Walker, M.D., Secretary.*

Cortland County

Dr. John M. Swan, Rochester, executive secretary of the New York State Committee of the American Association for the Control of Cancer, was the speaker at a meeting on February 27 at the Truxton Central School gymnasium in Cortland. The meeting was arranged through the Cancer Committee of the county society.

Delaware County

The National Youth Administration has been given the job of making Thomas splints and Everett arm splints for the County Emergency Medical Committee. Dr. Donald Davidson, chairman, is sponsoring the job order. This job order has been approved by the District Office, according to the *Stamford Mirror Recorder*, in which the article appeared.

NYA has also received an order for nine (9) ticks and nine (9) stretcher covers from the Walton Chapter of the American Red Cross.

Any other chapter of the American Red Cross or organization doing Civilian Defense work who needs any type of work done, if they will contact Lockhart Russell at the Post Office Building in Walton, New York, the NYA would be glad to do the work. The cosponsor provides the material and the National Youth Administration furnishes the labor at no cost to the cosponsor.

Erie County

Industrial Health was the subject of a symposium held in Buffalo on February 26. It was presented under the auspices of the Medical Society of the County of Erie; the University of Buffalo School of Medicine; the Division of Industrial Hygiene, New York State Department of Labor; the New York State Department of Health; and the Medical Society of the State of New York.

The meeting was called to order by Dr. Her-

Tioga County

See page 557 for postgraduate lectures.

Schenectady County

At the regular meeting held on March 3 the

business session was followed by an address on "Blood and Plasma Transfusions—General Considerations." The speaker was Dr. August Korkosz, director of the Blood Bank of the Ellis Hospital, Schenectady.

WORK, BUT SING TOO!

Flung and pushed about as so many of us are at this time, it is brought home to us with great emphasis that one of the few important possessions to treasure and guard zealously is mental and spiritual poise. From the time we arise to the moment we fall asleep, by radio and newspaper, in conversation and in conferences, at our work, yes, and at our lodge and club meetings, at the theater, and even in church, we are not only bombarded with friendly and unfriendly propaganda, but we are dogged perpetually to contribute money liberally, and give our little recreation time more and more, as "overtime," to defense and war activities.

This is inevitable of course. It must be that we shall all work hard together. Our President found it necessary to warn us that we are not beginning to produce enough, and that we must labor longer hours. As good citizens we must put our savings into Defense Bonds, we must keep keen our enthusiasm and our neighbor's enthusiasm, all bent toward achieving the success of Democracy's cause—more than even that, Democracy's life.

And all this time not a word is uttered about keeping mentally well, by not overworking our emotions but by taking time out to play, to laugh with children, and even to pray. It is no time, we are told, to be cautious; but it is still a step from sanity to insanity. It is very easy to snap under the strain of excitement, to spin about and tumble over the cliff of sanity. The climb back from the bottom is hard. . . .

—K. P. H. Wilson, R.N.,
in *Mental Hygiene News*

"DEATH TAKES HOLIDAY"

"There never was a time, probably, when so many events reflect the remarkable scientific advances in medical practice. Following are very brief excerpts from recent *Science News*:

"Deaths from acute appendicitis with perforation or rupture of the appendix have been reduced to less than five out of every 100 by the use of sulfathiazole in addition to immediate operation. . . .

"Patients with broken bones in which the skin and other tissues are also broken open and infected with germs, a common condition in war injuries and automobile accidents, may be saved by sulfanilamide crystals implanted in the wounds. . . .

"Wounds heal poorly after an operation and are likely to break open when the patient has been getting too little vitamin C, the vitamin found in tomatoes, citrus fruits and other fruits and vegetables. . . .

"A new supplementary instrument to help the surgeon look into the body and actually see an appendix or a bleeding stomach ulcer before he operates has been announced.

"Synthetic antibleeding vitamin K acts so swiftly that within two hours after giving it patients previously in danger of fatal hemorrhage can be safely operated on. . . .

"That a decline in pneumonia deaths during an influenza epidemic occurred, for the first time on record, during the winter of 1940-41, is announced by the Metropolitan Life Insurance Company. Sulfadiazine treatment seems to have largely replaced serum treatment. . . ."

—S.C.A.A. News

New York County

At the meeting on February 23 the following symposium on war surgery was heard: "Fractures," Dr. William Darrach; "Wounds," Dr. John J. Moorhead; "Abdominal Injuries," Dr. Chas. Gordon Heyd; "Chest Injuries," Dr. Harold Neuho; "Brain Injuries," Dr. Foster Kennedy; and "Spine Injuries," Dr. Byron Stookey.

A recent editorial in the *Journal of the Medical Society of the County of New York* provoked comment in several New York City newspapers. "Using the Emigre Doctor" was the title of this excellent piece. It began: "As a result of military requirements, civilian America faces an imminent shortage of medical men. Yet at least 1,500 physicians, some of them graduates of Europe's leading medical schools, are vegetating in idleness, barred from the practice of their profession and unable to serve the country which has given them refuge and the cause in which they believe. *Common sense, as well as the American tradition of opportunity, demands that we utilize this skill which is now going to waste and of which the nation has need.*"*

The Hermann M. Biggs Memorial Lecture, which is held annually in Hosack Hall at The New York Academy of Medicine under the auspices of the Committee on Public Health Relations, will be delivered this year on Thursday, April 2, at 8:30 p.m. by Dr. James S. McLester, professor of medicine at the University of Alabama, chairman of the Council on Foods and Nutrition of the American Medical Association, and chairman of the Subcommittee on Medical Nutrition of the National Research Council. The lecture, "Nutrition and the Nation at War," is open to the general public.

Niagara County

The county society is sponsoring jointly with the Nutrition Committee and the Civilian Defense Council an extensive nutrition program for Niagara Falls.

Oneida County

The growth of the colony system of treating mental defectives was recently explained by Dr. Ward W. Millias, clinical director of the Rome State School, to the Utica Academy of Medicine.

Advances in aiding and restoring the hearing of deaf persons were explained by Dr. Samuel J. Kopetzky, president of the Medical Society of the State of New York, and members of the staff of the research department of the New York Polyclinic Hospital.

Persons suffering from deafness must be treated from a psychologic angle, he said, since a depressive condition results not generally found in blind people. He also urged all doctors to respond to the call for medical service in the armed forces.

Onondaga County

Thirty members of boards of supervisors from Allegany, Barry, Eaton, and VanBuren counties in Michigan were guests of Syracuse University at a one-week institute which began on February 23. It was conducted as a contribution to the Michi-

gan Community Health Project of the W. K. Kellogg Foundation at Battle Creek, Michigan.

The supervisors studied medical service, county government, education and home economics, welfare, library service, and democratic process under the auspices of the Institute. The New York State Department of Health cooperated with Syracuse University in sponsoring the Institute. Units of the University which conducted various sessions include the Maxwell School of Citizenship and Public Affairs, College of Medicine, School of Library Science, School of Speech, College of Home Economics, and School of Extension.

Dr. John B. Alsever, Syracuse, recently left for Washington, D. C., where he will supervise the establishment of plasma banks throughout the United States. Dr. Alsever, a member of the faculty of the College of Medicine, Syracuse University, will serve as technical consultant to the medical division of the Office of Civilian Defense.

Dr. Alsever has done considerable research in the use of plasma. In the January 15, 1941, issue of the JOURNAL there was published an article by Dr. Alsever and Dr. Robert B. Ainslie entitled "A New Method for the Preparation of Dilute Blood Plasma and the Operation of a Complete Transfusion Service."

Queens County

On February 24 a dinner at the Forest Hills Inn preceded the meeting in the Medical Society Building. The scientific program included a talk by Dr. Harry Gold on "The Circulation in Pneumonia." Dr. Norman Plummer spoke on "Specific Therapy of Pneumonia," and Dr. McKen Cattell, on "The Pharmacology of the Sulfonamides."

A sound motion picture entitled *Thumbs Up* was shown before the addresses. The picture is sponsored by the British War Relief Society, Inc., and is the classic film portrayal of war and relief and demonstrates with dramatic force the violence of total war. It follows the train of brutal Nazi aggression across the whole face of Europe, starting in Poland and driving ruthlessly through tragic scenes which reach their climax at Dunkerque, with its epic violence and heroism. Against this flaming background, the humanitarian work of the British War Relief Society is silhouetted. Lowell Thomas is the commentator.

Richmond County

Dr. William H. Best, deputy health commissioner, was one of two speakers at a meeting of the county society on February 11 in the Health Center, St. George.

Dr. Best told the doctors that in the entire city last year there were 363 diphtheria cases and 10 deaths, including 33 cases and 4 deaths on the Island.

"The present diphtheria situation on Staten Island is grave enough to require the combined efforts of the practicing physicians and all public and private agencies concerned directly or indirectly with the health and welfare of our children," he said.

The other speaker, Dr. Michael Antell, borough health officer, announced plans for a diphtheria control campaign on Staten Island.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

An Important Amendment to the Education Law

AS IS well known, the Education Law has for many years forbidden the practice of medicine by any person who is not lawfully licensed or authorized to practice medicine within the State of New York. For many years, the said Law has contained a section providing that its provisions and restrictions should not affect or prevent "the practice of medicine in a legally incorporated hospital by a duly appointed member of the resident staff or by an intern while actually serving in a state hospital or other state institution in which medical service is provided."

However, while the Law acquiesced in the practice of medicine by resident physicians or interns, it made no attempt to define the qualifications of such resident or intern which would entitle him to act in such capacity.

At a recent session of the Legislature, steps were taken to incorporate into the Law provisions whereby a standard of educational training is set up as a condition to the practice of medicine by interns and resident physicians and of work in hospitals by medical students. The provision of said section of the Law which was enacted with a provision that it should become wholly effective July 1, 1942, are, so far as relevant, the following:

"This article (Education Law) shall not be construed to affect or prevent the following:

... (2) the practice of medicine in a legally incorporated hospital by a physician duly appointed as member of the resident staff or by an intern while actually serving in a state hospital or other state institution in which

medical service is furnished, provided the said duly appointed member of the resident staff or intern has completed not less than four satisfactory courses of at least eight months each in a medical school in this country or Canada registered as maintaining at the time a standard satisfactory to the department, or in a medical school in a foreign country maintaining a standard not lower than that prescribed for medical schools in this state, or has received the degree of bachelor or doctor of medicine from some medical school in this country or Canada registered as maintaining at the time a standard satisfactory to the department, or a medical degree or diploma from a medical school in a foreign country maintaining a standard not lower than that prescribed for medical schools in this state, or a license to practice medicine in a foreign country issued under requirements not lower than those exacted for a medical license in this state; or ... (10) medical students performing clinical clerkships or similar functions in a legally incorporated hospital, state hospital, or other state institution, provided such students are matriculated and enrolled in a medical school in this country or Canada registered as maintaining at the time a standard satisfactory to the department, or in a medical school in a foreign country maintaining a standard not lower than that prescribed for medical schools in this state."*

* Education Law, Section 1262.

Inquiries

YOUR Counsel recently received the following inquiry:

"Dear Mr. Brosnan:

"We are very anxious to be absolutely certain whenever permission for an autopsy is obtained at this hospital, that we are living up to the letter of the law. We wish to be sure, for example, that the person who signs the permit is legally entitled to give permission for the autopsy and that we, ourselves, do not in any way infringe upon the right of the next of kin in making our examination.

"Does the law permit hospitals or medical schools in New York State to remove entire organs or major portions of them for teaching purposes or for the building of a pathologic museum? If the pathologist is not permitted to remove an entire organ as a specimen for teaching purposes, is there any way in which the autopsy permit may be so worded that he is entitled to keep such a specimen?

"If a patient who comes to the hospital is married but is not living with her spouse and

gives as the next of kin the name of her sister, does the sister have a legal right to grant permission for an autopsy without permission from the spouse?

Yours very truly,"

Your Counsel's reply was as follows:

"Dear Doctor:

"I acknowledge receipt of your letter in which you make certain inquiries concerning the law of this state applicable to the performance of autopsies.

"I believe that Section 2210 of the Penal Law establishes in New York State the right of a person during his lifetime, by will or otherwise, to direct that an autopsy may be performed on his body. Said Section provides as follows:

"Right to direct disposal of one's own body after death. A person has the right to direct the manner in which his body shall be disposed of after his death; and also to direct the manner in which any part of his body, which becomes separated therefrom during

his lifetime, shall be disposed of; and the provisions of this article do not apply to any case where a person has given directions for the disposal of his body or any part thereof inconsistent with those provisions.'

"The Section 2213 of the Penal Law specifically provides instances in which an autopsy may be performed, and Section 2214 provides that any person who participates in the performance of an autopsy except by authority of law, or pursuant to permission given by the deceased, is guilty of misdemeanour. The Section 2213 provides as follows:

"The right to dissect the dead body of a human being exists in the following cases:

"1. In the cases prescribed by special statutes; or,

"2. Whenever a coroner is authorized by law to hold an inquest upon a body, or upon the written request of the duly constituted police authorities of the state, including the department of correction, or of a political subdivision of the state with a population of more than one hundred thousand persons, or on behalf of the police authorities of a political subdivision of the state with a population of less than one hundred thousand by request of the state department of correction or state police, so far as such coroner authorized dissection for the purposes of the inquest, or to furnish the information desired by said police authorities, and no further; or,

"3. Whenever and so far as the husband, wife, or next of kin of the deceased, being charged by law with the duty of burial, may authorize dissection for the purpose of ascertaining the cause of death, and no further; or,

"4. Whenever any district attorney in this state, in the discharge of his official duties, shall deem it necessary, he may exhumate, take possession of, and remove the body of a deceased person, or any portion thereof, and submit the same to a proper physical or chemical examination, or analysis, to ascertain the cause of death, and the same shall be made on the order of any justice of the supreme court of this state, or the county judge of the county in which such dead body shall be, which order shall be made on the application of the district attorney with or without notice to the relatives of the deceased person or to any person or corporation having the legal charge of such body, as the court may direct. Said district attorney shall have power to direct the sheriff, constable, or other peace officer in this state, or to employ such person, or persons as he may deem necessary to assist him in exhuming, removing, obtaining possession of, and examining physically or chemically such dead body or any portion thereof. The expense therefor shall be a county charge, to be paid by the county treasurer on the certificate of the district attorney.'

"In addition to the said provisions of the Penal Law, Section 316 of the Public Health Law, in a Section relative to disposition of cadavers, provides for the performance of

autopsies upon unclaimed corpses and for the delivery of such corpses to medical colleges throughout the state. The said Section provides as follows:

"*Cadavers.* 1. Dissection. The persons having lawful control and management of any hospital, prison, reformatory, asylum, almshouse, morgue, or other receptacle for corpses not interred, and every undertaker or other person having in his lawful possession any such corpse for keeping or burial may deliver and he is required to deliver, under the conditions specified in this section, every such corpse in their or his possession, charge, custody, or control, not placed therein by relatives in the usual manner for keeping or burial, to the medical colleges, schools or institutes registered by the regents of the university of the State of New York as maintaining a proper standard, and universities of the state authorized by law to confer the degree of doctor of medicine and to all other colleges or schools incorporated under the laws of the state for the purpose of teaching medicine, anatomy, or surgery to those on whom the degree of doctor of medicine has been conferred, and to any university of the state having a medical preparatory or medical postgraduate course of instruction. No corpse shall be so delivered or received in case the next of kin, within forty-eight hours after death, notifies the person or institution so delivering or receiving the same, that it is desired for interment, or of a person who shall have expressed a desire in his last illness that his body be interred; and in such cases the same shall be buried in the usual manner. Any person claiming any corpse or remains for interment as provided in this section, may be required by the persons, college, school, institute, or university or officer or agent thereof, in whose possession, charge, or custody the same may be, to present an affidavit stating that he is such relative and the facts and circumstances upon which the claim that he is such relative is based, and that the said relative assumes the cost of burial, the expense of which affidavit shall be paid by the persons requiring it. If such persons shall refuse to make such affidavit, such corpse or remains shall not be delivered to him but he shall forfeit his claim and right to the same. Any such medical college, institute, school, or university desiring to avail itself of the provisions of this section shall notify such persons having the control and management of the institutions and places heretofore specified, and such undertakers and other persons having any such corpse in their possession, custody, or control in the county where such college, institute, school, or university is situated, and in any other county in the state in which no medical college, institute, school, or university is situated, or in which no such medical college, institute, school, or university desires to avail itself of the provisions of this section, of such desire, and thereafter all such persons shall notify the proper officers of such college, institute,

school, or university whenever there is any corpse in their possession, custody or control, which may be delivered to a medical college, institute, school, or university under this section, and shall deliver the same to such college, institute, school, or university. If two or more medical colleges, institutes, schools, or universities are entitled to receive corpses, under the provisions of this act and shall have given notice as aforesaid, they shall receive the same in proportion to the number of matriculated students in each college, institute, school, or university who are pursuing courses of anatomy and surgery at the time of making the apportionment. The professors and teachers in every college, institute, school, or university receiving any corpse under this section shall dispose of the remains thereof, after they have served the purposes of medical science and study, in accordance with the regulations of the local board of health where the college, institute, school, or university is situated. Every person neglecting to comply with or violating any provision of this section, shall forfeit to the local board of health where such non-compliance or violation occurred, the sum of twenty-five dollars for every such non-compliance or violation, to be sued for by the health officer of such place, and when recovered to be paid over, less the costs and expenses of the action, to such board for its use and benefits.

"2. Autopsies. The person having lawful control and management of any hospital in which a patient has died may order the performance of an autopsy upon the corpse, unless objection is made to such autopsy by the next of kin within forty-eight hours after death. In case of unclaimed bodies, the aforementioned medical colleges, institutes, schools, or universities shall have a priority claim to the bodies, for the purpose of teaching anatomy.

"3. Disposal of remains. In all cases in which an autopsy or dissection has been made of an unclaimed body, the provisions of article one hundred and ninety-eight of the penal law requiring the burial of a dead body and punishing interference with or injuries to it, shall apply equally to the remains of such body as soon as the lawful purposes of such autopsy or dissection have

been accomplished, except that the persons having possession of the dead body may, in their discretion, cause it to be either buried or cremated, or may retain parts of such body for scientific purposes."

"In answer to your inquiry concerning the removal of entire organs or major portions of them by hospitals and medical schools, let me state that I believe that where Article 316 of the Public Health Law is applicable Medical Colleges which receive cadavers are entitled to dispose of any portions of the said corpses for teaching purposes, or for the building of pathological museums. However, it should be noted that Section 316 of the Public Health Law only applies in special instances. In the ordinary case where a consent to an autopsy is obtained, or where an autopsy is authorized by the coroner or medical examiner, the law places a specific limitation upon the right to dissect a dead body.

"The scope of the autopsy is limited in the one case to 'dissection for the purpose of ascertaining the cause of death and no further,' and in the other case to 'dissection for the purpose of the inquest and no further.' Consequently, the ordinary rule seems to be that the organs must be replaced in the body after suitable specimens have been taken for the purpose of ascertaining the cause of death.

"I believe that under Section 2210 the Penal Law, set forth above, would permit a person during his lifetime to direct that any organ, or part of his body, might be dissected or preserved for study. In the case, however, where the surviving spouse or the next of kin authorize an autopsy, strict compliance with the wording of the statute would seem to forbid the keeping of specimens from a dead body, other than necessary for the purpose of ascertaining the cause of death.

"Your letter also raises the question as to the situation present when the surviving spouse is separated from the deceased and where the sister of the deceased consents. Under such circumstances I do not believe that ordinarily the sister would be entitled to consent to the autopsy but feel that the consent of the surviving spouse to an autopsy should be obtained even where the deceased and the surviving spouse were separated before death.

Very truly yours,"

CHICAGO SELECTED FOR 1942 CLINICAL CONGRESS OF THE AMERICAN COLLEGE OF SURGEONS

Because of the war, the thirty-second annual Clinical Congress of the American College of Surgeons will be held in Chicago, October 19 to 23, instead of in Los Angeles as originally planned. Headquarters will be at the Stevens Hotel. The

twenty-fifth annual Hospital Standardization Conference sponsored by the College will be held simultaneously. The programs of both meetings will be based chiefly on wartime activities.

Cardiac Failure!

The quickly available, powerful stimulation of Strophalen (Tosse) is called for in cardiac emergencies. Strophalen, injected intravenously, acts directly upon the heart muscle fibre, imparting sudden energy to the flagging organ. The diastole is prolonged, so that the pulse becomes less rapid. Strophalen tends to regulate the heart beat and improve cardiac muscle tone and contractility.

ALSO FOR CHRONIC HEART CASES

Strophalen provides the active principle of ouabain—identical in chemical structure and therapeutic action with the glucoside *g-strophanthin*. It is water soluble, fixes in tissue only slightly, is eliminated rapidly and has little cumulative tendency. Hence, Strophalen is notably suited to protracted medication in chronic cardiac conditions.

Supplied in 1 cc. ampuls; boxes of 6, 30, 100. Send for professional literature to Dept. 2.

Woman's Auxiliary

To the Medical Society of the State of New York

News from Capitol Hill

THIS is your Legislative Correspondent reporting from Capitol Hill in Albany. Medically speaking, things have been rather quiet so far—at least on the surface. We have had no all-out call for auxiliary action against any particular bill. In fact, I was looking hopefully for some high, wide, and handsome bills on the subject of defense, but nine out of ten of the ones we are interested in have come along on the "business as usual" basis.

Don't let that make you feel I am bored with my job; it is all new—all different—and all interesting as far as I am concerned.

We are interested in the passage of the X-Ray Bill introduced by Dr. Muzzicato (S. Int. 680 Muzzicato—A. Int. 1016 Sullivan). This limits the use of x-ray for diagnosis to doctors, dentists, and chiropodists. Then, there are a few bills that are being actively opposed by the Medical Society. One proposes to increase the time limit for malpractice suits from two to six years (S. Int. 66 Feinberg—A. Int. 61 Reoux). Almost anyone can fall apart in six years and a good lawyer could facilitate the process. Then there is a bill (A. Int. 308—Austin) to allow physical therapists to practice without the supervision of a doctor. This is certainly not in the interests of public health, for it would allow a physical therapist who has had no medical education to make diagnoses and would encourage the public to diagnose its own ailments.

For those who were under the impression that socialized medicine died with the defeat of the Wagner Bill and certainly would not be resurrected now that its author is in the army, let me point out that Mr. Gittleston (A. Int. 153) rattles the skeleton. His bill for state medicine, called by Haven Emerson the only pure state health plan, has been introduced for the fifth time into the Assembly.

It has been pointed out to us that while we in Albany have been vigilantly guarding the front door to organized medicine, various factors in Washington are at work to open the back door. Should the chiropractors be able to break down

resistance to their inadequate training and receive medical commissions in the Army—here we go again, what is good enough for our boys will be good enough for us—and all the work we have done to show that they are not educated to carry on the practice of medicine as they wish will be for naught. A pass key may be slipped in the back door in the form of an executive order that would amend the National Social Security Law to allow \$3.00 a day for hospital services.

And now, because all reporters have a yen to be commentators, I want to urge you to look ahead to your own future. Capitol Hill can be compared to Vesuvius. Though legislation is the final eruption, look at what precedes that earthquake. Our husbands are going to war in ever-increasing numbers; our taxes are more than we have ever known them to be. When it is all over, our men will come back to practices that are gone. Can't you see that the time will be ripe for the government to say: "Here I'll give you \$2,500 a year and maintenance, or \$5,000 if you are a specialist, to work for me?" And without any kick at all a large number of our doctors will jump at it as the quickest, easiest way to be self-supporting again. The taxes will stay up. Oh, they will take off some of the spectacular ones on cosmetics and the movies. Don't forget we never lost the income tax after the last war! So, we keep our taxes and we take state medicine with hardly a quiver. Legislation will prove just the final amen to that chapter.

Is that logical? It is a possibility? Is it far-fetched? Ask for yourself. Find out if any plans are being considered in your locality. Our greatest sacrifices will come after the war is won; when help must be provided by the medical societies to the returning doctor lest he be forced to sell his birthright of free competitive medicine for the proverbial mess of pottage—state control. Let organized medicine look to the peace as well as the war.

MRS. ALFRED L. MADDEN
Chairman of Legislation

General News

The Midwinter Executive Board Meeting of the State Auxiliary was held at the DeWitt Clinton Hotel in Albany on February 16 and 17. A social hour preceded the dinner on Monday night. At 8:00 P.M. a large group of the auxiliary members attended a session at the legislature. On Tuesday the Executive Board Meeting was held, Mrs. George B. Adams graciously presiding. Fine reports were read from the standing committees and the county presidents.

The Annual Convention of the Woman's Auxiliary to the Medical Society of the State of New York will be held on April 27, 28, 29, and 30 at the Waldorf-Astoria Hotel, New York City.

Headquarters will be in the Starlight Roof. All doctors' wives, whether members of an auxiliary to a county society or not, are urged to register at the Registration Desk in the corridor eighteenth floor, Starlight Roof, and are cordially invited to participate in all parts of the program.

Don't forget the National Convention.—Haddon Hall will be the headquarters for the Annual Meeting of the Woman's Auxiliary to the American Medical Association, which will be held in Atlantic City, New Jersey, June 8 to 12.

Requests for reservations should be sent immediately to Haddon Hall, Atlantic City, New Jersey.

No Lack in Biolac!

WITH THE sole exception of vitamin C, Biolac provides completely for the formula needs of normal infants throughout the entire bottle period. From the time when infants consume a full quart of formula per day, here's how certain essential food factors supplied by Biolac feedings compare with the minimal nutritional requirements recognized by the U. S. Food and Drug Administration.

	MINIMAL REQUIREMENTS	BIOLAC FEEDINGS
PROTEIN (gms./lb. body weight) . . .	1.4 to 1.8*	2.2†
CALCIUM (gms./day)	1.0*	1.0
IRON (mgms./100 calories)	0.75 . . .	1.25
VITAMIN A (U.S.P. Units/day)	1500. . . .	2500.
VITAMIN B ₁ (U.S.P. Units/day)	83.	85.
VITAMIN B ₂ (mgms./day)	0.5	2.
VITAMIN D (U.S.P. Units/100 calories) . .	50.	63.

*The Food & Drug Administration has not promulgated minimum requirements for protein and calcium in infancy. The values shown are those recommended by the National Nutrition Conference.

†When Biolac formulas are fed in the amount of 2½ fl. oz./lb. body weight.

Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrate of vitamins A and D from cod liver oil, and ferric citrate. Evaporated, homogenized, sterilized.

REVIEWED

The Spectacle of a Man. By John Coignard. Octavo of 252 pages. New York, Duell, Sloan and Pearce, 1941. Cloth, \$2.50.

A physician, a psychoanalyst, writes a novel. The theme is love. The patient, a male neurotic, falls in love with a beautiful woman. This new experience and his reactions to it constitutes the chief attraction of the novel. The author employs the method of psychoanalysis. The patient who is obsessed with many phobias, remains under treatment for one year and recovers. The manner in which psychoanalysis is applied to explain dreams and other symptoms of the patient will doubtlessly interest many a lay reader. It is a clever piece of work.

JOSEPH SMITH

Fatal Partners: War and Disease. By Ralph H. Major, M.D. Octavo of 342 pages, illustrated. Garden City, Doubleday-Doran & Company, 1941. Cloth, \$3.50.

Rare it is that a book submitted for review is read from cover to cover.

Here is the exception. Furthermore, it will be so read by anyone who picks it up. The reader is certain to be carried along by its popular style, enriched with historical fact, colorful anecdote, and the atmosphere of war and conquest.

No attempt is made to prove any thesis that great discoveries emerge from the tragedy of war. Instead, Major states the medical problems associated with the wars of the past, throwing light on aspects of warfare differing from its technic and tactics.

The volume opens with a chapter on Greece and Rome and their respective wars and pestilences: the plague of Athens (probably typhus) of the Peloponnesian War, and the smallpox of the Mesopotamian campaign that returned to ravage the Roman empire for fifteen years.

The eight Crusades (1096 to 1292) spread loathsome leprosy, resulted in decimating outbreaks of scurvy but, on the other hand, led to the development of hospitals of the Knights of St. John, those Knights Hospitallers whose splendid work of mercy has carried down to the present time.

The gunpowder era elevated the common foot soldier, changed the type of battle wounds, and gave us the surgical teachings of Berengarius, Paracelsus, and Galen.

The Thirty Years' War developed frightful epidemics of typhus and plague, these playing a large part in the sad tale of plunder, pillage, and pestilence. Napoleonic wars produced outbreaks of trachoma, bubonic plague, scurvy, typhus, and typhoid but also gave to the world Larrey and his "ambulances volantes."

The Crimean War developed the nursing of Florence Nightingale, and the one battle of Solferino resulted in the humanitarian organization of the Red Cross of Henry Dunant (1863).

Intensive study of the epidemiology of typhoid, malaria, and yellow fever followed our Spanish-American War and the Boer War with its ravages

of typhoid fever. Out of it all came anti-typhoid vaccination and regulatory control of yellow fever and malaria.

Shell shock, trench fever, typhus fever, gas gangrene, tetanus, war edema, Spanish influenza: these were outstanding medical problems of the first World War.

The Spanish Civil War brought the story of exceptional cruelty among brothers but gave us the new Winnett Orr-Truett treatment of wounds and the airplane ambulance. Now World War II gives us shell shock, "shelter fever," and the brilliant sulfonamide treatment of infections and wounds.

War and disease are indeed fatal partners. Fortunate the world if any remediable measures emerge from the Hell!

FRANK BETHEL CROSS

Effective Living. By C. E. Turner, A.M., and Elizabeth McHose, M.A. Octavo of 432 pages, illustrated. St. Louis, C. V. Mosby Company, 1941. Cloth, \$1.90.

This is a book primarily designed for use in the teaching of health education to a group of high-school age. The salient features of both personal and community hygiene are well presented. Without too much debate, a sufficient account is given of such basic subjects as anatomy, physiology, etc., to enable the student to rationalize his information on the subject matter presented. Controversial items are so treated that extreme opinions are eliminated.

F. L. MOORE

Masochism in Modern Man. By Theodor Reik. Translated by Margaret H. Beigel and Gertrud M. Kurth. Octavo of 439 pages. New York, Farrar & Rinehart, Inc., 1941. Cloth, \$4.00.

Masochism was first used to describe a sexual aberration—a perversion that Freud called the most frequent and most significant of all perversions, one in which an individual gets satisfaction by assuming a most passive relation to the partner, experiencing pain, suffering, and humiliation at the same time. However, the term has assumed a much broader implication, and it is now also used to describe a particular attitude toward life or a type of social behavior in which the individual seems to enjoy one's own suffering, dependency, or helplessness. Masochism, therefore, has outgrown its narrower sexual meaning, in which one derives satisfaction from one's love life in physical or mental pain, and is now used to describe the social situation in which a person unconsciously strives for physical or psychic pain, voluntarily submitting to suffering, and apparently deliberately accepting sacrifices, shame, humiliation, and disgrace.

The author has been a friend and associate of Freud for many years. He has included the views of Freud, as well as his own, regarding this rather perplexing mental mechanism of getting satisfaction from suffering. He sheds

REMEMBERING NAMES

Doctors meet more people—at least more than the rank and file of persons and perhaps more than many busy business men.

A good percentage of the profession have an almost uncanny knack for remembering the names of their patients even after just the first visit and after long intervals between visits. The patient expects his physician to show a discriminating interest in him, regardless of how large a practice the doctor may have. The most flattering thing to a layman is to be recognized by name as well as by ailment the minute he or she steps into the office.

According to a writer giving advice on introducing people—in Europe, people always repeat their own names after an introduction. If you form the habit of working in the name of your new patient in the first few minutes of conversation, you will be training yourself to remember names.

There are few more valuable talents in life if one wishes to be successful. The sound of a person's own name is one of the sweetest he can hear—written it should be spelled correctly and spoken it must be pronounced right, for nothing is more damaging than to garble another's name.

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

considerable light not only on some forms of neurotic and psychotic conduct but also on some illogical forms of apparently normal behavior not only of individuals but also of certain groups. Thus, one may gain some understanding of the submission of certain individuals to the will of gangsters or of some of the conquered peoples to the dictator countries. It may enable us to understand the submission of peoples to the totalitarian dictatorships. The book may shed considerable light in understanding the mental mechanisms of the isolationists and others who regard as futile any effort to fight the dictators.

The book is a profound study of a most difficult subject. It will receive a cordial welcome from all intelligent people.

IRVING J. SANDS

Infantile Paralysis. A Symposium Delivered at Vanderbilt University, April, 1941. Octavo of 239 pages, illustrated. New York, the National Foundation for Infantile Paralysis, 1941. Cloth.

This book is made up of six lectures delivered at Vanderbilt University in April, 1941. Recent advances made in the research of acute anterior poliomyelitis are discussed by six scientists.

In the first lecture, Paul F. Clark, Ph.D., of the University of Wisconsin, gives a history of the disease up to the present time.

Lecture 2: Charles Armstrong, M.D., of the U. S. Public Health Service brings up to date the literature and research on its etiology.

Lecture 3: Thomas M. Rivers, M.D. of the Rockefeller Institute, discusses the immunologic and serologic phenomena.

Lecture 4: The pathology and pathogenesis are well done by Ernest W. Goodpasture, M.D., of Vanderbilt University.

Lecture 5: John R. Paul, M.D., of Yale, discusses and illustrates the ideas evolved on the epidemiology of the disease.

Lecture 6: Treatment and rehabilitation are covered by Frank R. Ober, M.D., of Harvard.

In order to answer intelligently the myriad of questions by myriads of patients all physicians should become familiar with the contents of this little volume.

THURMAN B. GIVAN

The Care of the Aged (Geriatrics). By Malford W. Thewlis, M.D. Third edition. Octavo of 579 pages, illustrated. St. Louis, C. V. Mosby Company, 1941. Cloth, \$6.00.

The first edition appeared in 1919, and it has been seventeen years since the second one was published.

The book is divided into five sections; general considerations, miscellaneous medical problems, specific infections, noninfectious diseases, and pathologic conditions in old age. These subjects are fully discussed.

The public and medical neglect of the aged is commented upon and, in discussing the value of old age, an interesting account is given of the accomplishments late in life of many famous people. "One purpose of this volume is to stimulate physicians to look upon the old as still necessary to civilization and to stimulate the aged to carry on."

The importance of keeping senile patients out of bed, whenever possible, is emphasized, psychic as well as physical benefit being often obtained.

A chapter on tuberculosis in old people by Leroy S. Peters calls attention to the fact that this disease is not uncommon and is readily overlooked.

The book shows the great interest of the author in the problems of old people, and an extensive bibliography supports his statements.

W. E. McCOLLUM

Sulfanilamide and Related Compounds in General Practice. By Wesley W. Spink, M.D. Octavo of 256 pages. Chicago, Year Book Publishers, 1941. Cloth, \$3.00.

The Year Book Publishers are establishing a reputation for excellent books at low cost. We have previously had an opportunity to review very favorably their books on *Endocrinology* and *Vitamin Therapy*. Now comes Spink's excellent compend on sulfonamide therapy. This little volume contains a digest of most of the excellent work done by numerous workers and the author himself. There is even a section on sulfadiazine and sulfaguanidine which brings the volume right up to date. It cannot be too warmly recommended.

ANDREW M. BABEY

Handbook of Anaesthetics (Formerly Ross and Fairlie). Revised by R. J. Minnitt, M.D. Fifth edition. Duodecimo of 364 pages, illustrated. Baltimore, Williams & Wilkins Company, 1940. Cloth, \$4.00.

The fifth edition of this excellent handbook has been brought up to date by the extensive knowledge of Dr. Minnitt. It is essentially a practical book for the beginner seriously interested in the specialty of anesthesiology. Although many details of information are useful to the expert, he is likely to find that most of the material is rather elementary and simplified. The photographs and diagrams are plentiful and are of excellent quality. The small size of the book and excellent arrangement of the contents help to make this a good vade mecum for the intern and resident in anesthesiology.

BARNETT A. GREENE

A Text-Book of Pathology. Edited by E. T. Bell, M.D. Fourth edition. Octavo of 931 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$9.50.

This fourth edition of a *Text-Book of Pathology* is a timely contribution to the subject. Although departing in some beliefs and concepts that are held by other authors somewhat more orthodox, it nevertheless expresses the current thoughts clearly, concisely, and acceptably.

Many additions and important revisions have been made, bringing the work up to date. The illustrations are excellent and abundant and impress clearly on the mind points emphasized in the text. At the end of each chapter is a bibliography which, while not too cumbersome, offers a key to literature of the subject discussed. As a textbook for students and practitioners it should be placed in the first rank and find an enthusiastic welcome.

NEW YORK STATE JOURNAL OF MEDICINE

Copyright 1942 by the Medical Society of the State of New York

VOLUME 42

APRIL 1, 1942

NUMBER 7

Editorial

The Annual Meeting

Now for the first time in five and twenty years the annual meeting of the Medical Society of the State of New York, set for April 27-30 in the City of New York, will be held with the nation at war. Many of our members are already in the services, more are being called. Upon those who remain at their civilian posts a tremendous responsibility rests, and a burden of work which will tax everyone to the limit of his or her physical, financial, and mental ability. For this is a total war.

As might be expected, the general session which opens Tuesday, April 28, will deal with military medicine, Col. Chas. M. Watson, M.C., Surgeon, Second Corps Area, presiding, with Dr. Samuel Adams Cohen representing the metropolitan New York Chapter of the Association of Military Surgeons of the United States.

Major General James C. Magee, surgeon general, U. S. Army, will speak on the transition of civilian doctors to the status of medical officers of the army. Col. Leonard G. Rowntree, chief medical officer of the National Selective Service Administration, will tell of lessons learned from physical examinations of registrants. Dr. George Baehr, chief medical officer, Office of Civilian Defense, will talk about the physician's role in the civilian defense program.

Following the first general session on Tuesday, April 28, the one hundred and thirty-sixth annual meeting of the Society

will be formally launched at the banquet to be held in the ballroom of the Hotel Waldorf-Astoria at 7:00 P.M. The President of the United States, the Governor of the State of New York, the Mayor of the City of New York, and high-ranking representatives of the Army, Navy, and their Medical Corps, and of the Selective Service have been invited to attend. Owing to wartime demands, the President has been unable to accept the invitation, and a number of acceptances are necessarily tentative. However, significant addresses will be heard.

Anesthesia, industrial dermatoses, and a symposium on diseases of the chest will complete the first day's scientific session. A more than usually interesting display has been arranged by our friends the exhibitors who, even in this first year of war with priorities challenging their ingenuity, stand by us as they always have in the past under all conditions. We urge that all physicians who come to the meeting make it their business to examine the exhibits carefully. It will be to their interest to do so, since no one can tell what the forthcoming year will hold in store in the matter of shortages, even of necessary medical apparatus and supplies of all sorts.

The entire program is printed elsewhere in this issue and includes such high lights as a symposium on lupus erythematosus, and one on the various diarrheas; a joint meeting of the section on medicine with the section on surgery; and

an interesting presentation, in the section on neurology and psychiatry, of experiments with "glue suture" in repair of nerve injuries, by Dr. Nilson de Rezende, of Rio de Janeiro.

A symposium on public health and the war and another on chest film interpretation will also be held. Radiologists throughout the state have been asked to send in films of interesting, unusual, or puzzling cases in which the diagnosis has been proved by microscopic study, operation, or autopsy. For the first time, the section on pathology and clinical pathology will present a demonstration of fresh pathologic material. Surgery

in the aged will be discussed by Dr. Frederick W. Bancroft. The subject of refrigeration as a means of anesthesia on surgery of the extremities should be interesting to many, and to those who delve into the history of medicine, a paper in body snatching in New York City should prove of interest, as well as one on the yellow fever epidemic of 1795-1805 in New York City. In the program of the session on the history of medicine we note the following: "Intermission: Epidaurian Oasis." Gentlemen, your guess is as good as ours. See you there? Bring your own palms—it may be only a mirage.

Calling the Old Guard

A correspondent writes:

"Medical men over sixty, with a practice of three or four decades behind them, are now about to be called from *otium cum dignitate* back to urgent medical service in practice, hospitals, and on the defense front, as the younger men in these same medical areas are drafted into military service.

"This will come within the next two or three months, and we must come down from our self-selected shelves of semi-isolation into the world of work and double work, and we must do our work well."

He then suggests that each ask himself two questions. The first: Am I physically fit to walk the wards and to do the work? The second: Am I up to date? Could I face a State Board examination?

The obvious answer to the first question is a health examination. We recommend it daily for others. Have we the moral courage to do it ourselves? "I am going to do my work well," says our correspondent, "even though I am facing the work of three men half my age. . . ." Surely this is a thing to which we in the sere and yellow leaf can pledge ourselves—namely, a survey (the American Medical Association blank costs but ten

cents) of our physical assets for the work we have to do.

The answer to the second question is not so simple. It involves the relative values of experience and quantitative information. The profession has sufficient journals and readily accessible sources of information to have been able to follow closely the developments in modern medicine if they have had the will to do so. Postgraduate refresher courses also have been provided in abundance, and still are. It is possible for any man in the profession who can read or hear to be reasonably up to date. And it is gratifying at any county or state society meeting to see the large proportion of gray (and sometimes bald) heads in attendance. The labor of being "up to date" has been made easy.

It is quite possible, in our view, that any physician who has attended the scientific sessions of his county society, has read his journals, and has attended the refresher courses, might fail a State Board examination, and still be reasonably up to date. The value in actual practice of three or four decades of work with human beings and medical procedures is inestimable. And we feel that the men over 60 who have the physical stamina to withstand the rigors of a re-

turn to more active practice will give a good account of themselves.

We urge the adoption of the health examination on all physicians, young or old, and add, modestly, the suggestion

that they carefully read this JOURNAL, as well as other journals published for their special interests, that they attend their county refresher courses, and that they take each day as it comes.

Security? What Security?

There is, apparently, no change in the point of view of the Administration with respect to the promotion of its social program. "Radical proposals for changing the whole system of American living,"¹ in sickness or in health, seem to be pending. We need planes, not social gains!

In his budget message to the second session of the Seventy-seventh Congress, January 7, President Roosevelt recommended "an increase in the coverage of old age and survivors' insurance, addition of permanent and temporary disability payments and hospitalization payments beyond the present benefit programs, and liberalization and expansion of unemployment compensation in a uniform national system." On January 20, 1942, a communication from the President was sent to the House of Representatives requesting \$300,000,000 for "extended unemployment compensation benefits." This recommendation apparently is not related to the proposed disability and hospitalization payments, but refers only to problems of unemployment occasioned by the changing of industrial plants from the production of peacetime goods to the production of war materials. Officially, this is the status of a recommendation thrown by the President recently into the whirlpool of public opinion. The discussion of the problem is agitating leaders in the fields of prepayment plans for medical care and hospitalization, hospital management, and medical practice.⁴

Public opinion at the present time is focused upon rising income taxes, shortages in consumer goods, rationing of rubber and sugar, and queries from the Pacific: Where are the planes?

In numerous addresses [continues the J.A.M.A.] and in hearings before legislative bodies since 1938, Mr. Arthur J. Altmeyer, chairman of the Social Security Board, has continued frequently to suggest cash benefits

to persons unemployed because of sickness and the provision of constructive social services to supplement cash aids, including medical care. Obviously every proposal for expansion of the social security program must, therefore, be viewed in the light of the ultimate goal set by Mr. Altmeyer. Even though the House of Delegates of the American Medical Association apparently approved unreservedly the principle of cash benefits for those sustaining loss of wages because of sickness, the provision of cash payments of \$3 a day to the worker who is hospitalized must be considered as part of a movement toward complete plans for compulsory sickness insurance on either a cash or a medical service basis.

We are as sympathetic to the "problems of unemployment occasioned by the changing of industrial plants from the production of peacetime goods to the production of war materials" as anyone else, including the President and the Social Security Board. We should like, however, to be more certain of the national security, as evidenced by the actual production and effective use of planes and other offensive war materials, before entertaining elaborate and "radical proposals for changing the whole system of American living in sickness or in health." In this we feel that we would be overwhelmingly supported by public opinion. It would not matter greatly what system of medical care prevailed in a defeated nation.

Too little and too late. These bitter words, leaving much unsaid, stand as a fitting monument to thinking which has not placed first things first. Then in France, for example, then in Britain, and now—

The new proposals of the President, apparently emanating from the Social Security Board, must not be viewed in the light of circumstances as they prevailed in 1938, but

¹ Editorial, J.A.M.A. 118: 820 (Mar. 7, 1942).

in the light of conditions as they exist today. The intervening period has witnessed an extraordinary expansion in voluntary hospitalization insurance and in so-called medical service plans. Today some fifteen million persons are insured against the costs of hospitalization in a variety of agencies, including private insurance corporations, mutual non-profit plans like the Associated Hospital Service of New York, and hospitalization plans set up on a nonprofit basis in various states. At least fourteen states and numerous counties have developed voluntary plans to cover the costs of medical care. An extensive experimentation is now in progress which should lead ultimately, if not too greatly disturbed, to the development of procedures distinctly American in their characteristics and wholly capable of meeting the needs for medical and hospital service. These are likely to be adapted to the American system of government rather than modeled after those plans of medical care and hospitalization which have prevailed in foreign countries, and which have been developed under concepts that are socialistic, communistic, or totalitarian rather than democratic.

There is a sickness, a sickness of the spirit, of the mind's eye, a legislative myopia, which seems to blur and distort the shape of distant things. Such as the war in 1941, for example.

Mr. Arthur J. Altmeyer stated his point of

view positively to the Congress when he said in July, 1941:

"Our eventual goal should be the establishment of a well-rounded system of social insurance to provide at least a minimum security to individuals and their families due to unemployment, sickness, disability, old age, and death. In addition, we must provide a series of constructive social services to supplement the cash aids provided under social insurance. Medical care should be available to individuals and their families so that we may build a healthier, happier nation. Such a system of medical care would be instrumental in reducing the costs of cash payments for sickness and disability."

Mr. Altmeyer speaks of a "minimum security to individuals and their families." We could wish that this could be guaranteed not by a "series of constructive social services to supplement the cash aids provided under social insurance," but by the maximum production of such things as ships, guns, tanks, and planes of which our industry is capable. After this is an accomplished fact, under a legislative and productive program which actually puts first things first, let us consider the matter of insurance—not before. Until then, is it too much to ask that medical services be left undisturbed under such a system as the physicians have developed and which seems to be working?

 *Buy U. S. Saving Stamps and Bonds* 

Reservations for the Annual Banquet

..... are now being made. Requests should be sent to Alfred M. Hellman, M.D., chairman, Banquet Committee, Medical Society of the State of New York, 292 Madison Avenue, New York City. Or, you can telephone—Murray Hill 3-9841. Tickets are \$5.00.

The banquet will be held in the Waldorf-Astoria Hotel on Tuesday, April 28, at 7:00 P.M.—a *must* occasion for everybody.

AUROTHERAPY IN LUPUS ERYTHEMATOSUS

A Study Based on a Further Experience of Fourteen Years

PAUL E. BECHET, M.D., New York City

IN 1890 a great impetus was given to the use of gold therapy. This was largely due to the statement of Robert Koch at the Tenth International Medical Congress in Berlin that potassium gold cyanide, even in such small dilutions as 1:1,000,000, prevented the growth of the tubercle bacillus in cultures. On Koch's invitation, von Behring made further investigations, and his results were confirmatory.

Brück and Glück¹ used potassium gold cyanide in cases of lupus vulgaris, but they also used tuberculin. They believed that they had observed an increase in the favorable influence of the gold on the lesions with the use of tuberculin. Bettman² also believed that the favorable influence was due to the combined use of tuberculin and potassium gold cyanide. Bue³ used gold chloride with good results in the treatment of persons with tuberculous adenitis. Feldt,⁴ in a series of monographs, reported the use of another gold compound, 4-amino-2-aurothiophenolcarboxylic acid. This was extensively used in both cutaneous and internal tuberculosis not only by Feldt but also by many other German investigators. Ruete⁵ reported complete healing in a case of acute lupus erythematosus after seven injections of the compound.

Martenstein⁶ used amino-aurothiophenolcarboxylic acid in the treatment of 42 patients, with cure in 28 and improvement in 6. Favorable results with amino-aurothiophenolcarboxylic acid were also reported by Fried⁷ and Ullmann.⁸

Møllgard⁹ stated that experiments with the different kinds of gold therapy were made on animals only by Kolle and Schlossberger¹⁰ "who were only able to show retardation of death of small tuberculous animals which were treated with krysolgan (amino-aurothiophenolcarboxylic acid) injections, and this retardation was not more pronounced than with the copper compounds or different derivatives of iodine."

It then remained for Schamberg, Harkins, and Brown¹¹ to publish their results with gold compounds in the treatment of animals with experimental tuberculosis of the skin. These

authors stated that they had observed a demonstrable effect on the cutaneous lesions after injections of gold compounds and in some of the animals a prolongation of life considerably beyond that of the controls. The same authors noted that a favorable influence was induced by gold therapy but that definite cures were not obtained. In their experiments they used such various gold compounds as sodium-gold-arsphenamine, gold-naphthol-blue, gold-hexamethylenaminthiosinamine, gold-hexamethylenamin-thiocarbamide, gold and sodium thiosulfate, and a gold protein compound.

In a later communication Schamberg and Wright¹² stated that they used gold and sodium thiosulfate in 24 patients suffering from lupus erythematosus with the following results: The lesions disappeared in 5 cases; in 6 cases they were practically healed; improvement occurred in 12 cases; and a number of patients were still under treatment. Only 1 patient did not show improvement. The authors stated: "For a disease which in the past has been so obstinate and intractable as to be regarded as the 'bête noir' of dermatologists, these results, to say the least, are noteworthy."

Whitehouse and Bechet¹³ in 1927 reported the use of gold over a period of four months in 30 cases of lupus erythematosus with the following results: complete disappearance of the lesions in 4 cases; 4 cases, practically well; 11, greatly improved; 10, slightly improved. Only 1 did not show improvement.

Rivelloni¹⁴ reported a cure in 6 of 16 cases, great improvement in 3, slight improvement in 6, and no change in only 1 case. Haxthausen¹⁵ treated 109 patients, with cures in 35 per cent and considerable improvement in 30 per cent. Scolari¹⁶ reports the highest percentage of cures: 25 (80.6 per cent) of 31 patients treated with 4-amino-2-aurothiophenolcarboxylic acid. Towle¹⁷ tabulated the largest number of cases of lupus erythematosus in which gold compounds were used, reporting 420 cases (319 in America), of which 163 (51 per cent) were cured, 134 (42 per cent) were improved, and only 22 were failures (6.8 per cent). Of 101 foreign cases, there were 46 cured (45.5 per cent), 49 improved (48.5 per cent), and 6 failures (5.94 per cent). Towle

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

believed that the 5.5 per cent increase of cures in the American cases was due to the increased efficacy of the American gold and sodium thiosulfate.

Strandberg¹⁸ reported 42 per cent cured, 27 per cent almost cured, and 20 per cent improved in a group of 84 cases of lupus erythematosus treated with gold compounds.

Wright,¹⁹ in a paper read at the Fifty-eighth Annual Meeting of the American Dermatological Association in 1935, stated the results obtained with aurotherapy in 76 patients with lupus erythematosus observed over a period of ten years. Of this number, 28 (37 per cent) were cured, 26 (34 per cent) were greatly improved, 13 (17 per cent) showed moderate improvement, and 9 showed no improvement.

Franklin²⁰ treated 31 patients with sanocrysin (gold sodium thiosulfate). Of the 31, 20 were cured, 4 were improved, and 7 remained unchanged. The period of observation of the cured patients covered two and one-half years.

Results of Treatment with Gold Compounds Based on Personal Observation

Since my first report on aurotherapy in 1927, I have observed therapeutic results from gold in approximately 125 dispensary cases and about 30 private patients. I shall make no attempt at tabulation because of its inherent difficulties in reference to therapy. Patients who disappear after inadequate attendance, those who come only at irregular intervals, and those who are totally indifferent to medical advice all contribute to these difficulties. Again, there is the question of definition. For instance, what signifies a "cure"? What does an author mean by "marked" improvement, "slight" improvement, etc.? It is all too elastic to be compressed into a table. It might well be that a cure could be claimed if the patient remains free from lupus erythematosus for five years after aurotherapy, yet I have observed, in private practice, a recurrence ten years later. For these reasons I shall at this time give you only a résumé of my own experiences with aurotherapy.

One of the most outstanding was the first case treated by me with gold. This patient, presented before the New York Dermatological Society on February 15, 1927,²¹ was a man, aged 50, who was suffering from lupus erythematosus of the chronic discoid type for twenty-three years. The entire face was involved with angry red, scaly, infiltrated lesions. He had been treated so vigorously with solid carbon dioxide, cauterants, and the roentgen

rays that throughout the active areas of lupus erythematosus there was a severe radiodermatitis and extensive scarring. Both ears had been so severely burned that one had been entirely removed because of extensive carcinomatous degeneration, and the other was partially destroyed by an active epithelioma which was still present. As gold sodium thiosulfate had not as yet been manufactured in America, I used a gold protein compound kindly sent me by Dr. Schamberg. Immediately after each injection the patient suffered a nitritoid crisis, followed by a rise of temperature and a severe local reaction at the site of the eruption, all of which subsided within twenty-four hours. These reactions did not seem to have any effect on his general health and, as the improvement, even from the first, was almost phenomenal, the injections were continued until supplies of gold sodium thiosulfate became available. With the use of the latter drug these nitritoid reactions ceased, and the improvement continued until, after several years of continuous treatment in which the patient received a total of some 15,000 mg. of gold sodium thiosulfate, he made a complete recovery. Seven years later he was still well, and when seen again about one year ago he had remained well for twelve years. The remaining epithelioma of his one ear had been excised some seven years previously without subsequent recurrence. He seemed in robust health. A check-up of his blood, urine, and chest showed normal findings. The administration of 100 mg. of gold sodium thiosulfate approximately once a week for several years had apparently caused no ill effect. It must be well understood, however, that this enormous dosage is not advised and was given at a time when it was thought perfectly proper to give such doses. However, it is my definite opinion that this spectacular therapeutic result was due to the excessive use of the drug and would not have occurred with our present-day doses of 50 mg. or less.

Another instructive case was presented by me before the Atlantic Dermatological Conference on December 16, 1925.²² The eruption consisted at first of large scaly plaques of lupus erythematosus over the face and upper part of the neck only, which had been present for one year. The patient's general health was excellent. The lesions were typical of the discoid type. Without my knowledge, the patient received a single but severe erythema dose to the face with the air-cooled quartz lamp, the chest and upper part of the

arms being left unprotected. A severe burn ensued, which immediately assumed the characteristics of an acute disseminate lupus erythematosus over the exposed area, and shortly thereafter lesions appeared on the extensor surfaces of both hands. Later on, he became quite ill, developed a chronic cough and lost much weight. A physical examination of the chest was negative. The sputum was free from tubercle bacilli, but roentgenograms showed a bilateral peribronchial thickening. After seven or eight injections of the gold protein compound, given me by Dr. Schamberg, in doses of 5 to 10 cc., the disseminate lesions had entirely disappeared, leaving only a few small scattered discoid lesions on the face. The patient's general condition improved rapidly; within a few weeks he gained more than 18 pounds in weight. Several months later he seemed to be in good health and stated that he felt entirely well. Other than burning and itching over the site of the eruption within twenty-four hours after treatment, there were no reactive manifestations.²³

This complete lack of untoward reactions in a severe case of disseminate lupus erythematosus might be attributed to the reasons advanced by Schamberg²⁴ in discussion of my paper in 1927, as follows: "My personal feeling is that in these cases it is better to use a gold protein compound, which has a much lower toxicity than the gold or silver thiosulfate and which may be sufficient to bring about a favorable result." Certainly, in this day we do not, and rightly so, use gold in acute disseminate lupus erythematosus with constitutional symptoms, but in the sub-acute disseminate type without any constitutional symptoms I have used it in small doses, keeping a careful check on the white blood cell count, the occurrence of pruritus, renal complications, or constitutional symptoms, and I have achieved excellent results.

An additional fourteen years of experience in aurotherapy in approximately 125 dispensary cases and 30 private cases has only enhanced my first opinion—namely, that in gold sodium thiosulfate we have an agent that despite occasional recurrences, occasional more or less severe reactions, and even at times complete failure in a small percentage of cases, is the best single remedy for lupus erythematosus. I shall not enter into a discussion of the relative merits of gold or bismuth in lupus erythematosus since it is not pertinent to this paper, but I must confess that in the inveterate types of lupus erythemato-

sis I have observed more frequent and permanent improvement when gold has been used.

The Question of Dosage in Relation to Its Efficacy

There is no doubt in my mind that we do not at present observe so much material improvement or so many cures from gold sodium thiosulfate as we formerly did, but I believe that this is entirely due to its use in smaller doses because of the well-founded inherent fear of the drug due to more or less severe reactions and even death. These reactions will be analyzed in another section.

Therapeutic results with gold sodium thiosulfate in my personal experience have not lessened with the passing of time. I have, through long experience, developed certain simple plans of procedure which seem to me to have greatly lessened the chance of accidents. From the beginning I have used only gold sodium thiosulfate, since I have found this preparation most trustworthy. My first dose is from 2 to 5 mg. and, in the absence of nitritoid reactions, leukopenia, pruritus or dermatitis, or renal irritation, the dose is raised weekly to 10, 25, 50, 75, and up to a maximum of 100 mg. My invariable rule when administering gold is to keep a watchful eye on the leukocyte count, on the occurrence of pruritus or dermatitis, or on the appearance of renal irritation, and I warn the patient about the danger of excessive actinic exposure. Leukopenia and pruritus especially are the danger signals in aurotherapy, and in their presence gold should be discontinued altogether. If this rule, first advocated by Weiss, Lane, and Bagby,²⁵ were invariably followed, a great many accidents could be avoided. Wright²⁶ states that when the leukocyte count is 6,000 or less he uses bismuth therapy to bring it up and, when it reaches a higher level, he safely substitutes gold therapy. This might prove an excellent practical suggestion, well worth further trial. I have leukocytic counts done at frequent intervals. In this way I have given thirty to sixty or more injections of gold of 100 mg. each, without accident. I have found that at times extensive improvement did not begin until twenty-five or even more injections had been given, so that I do not discontinue aurotherapy because of nonimprovement until at least twenty-five injections have been administered.

Following the method outlined, I have observed striking improvement and even com-

plete disappearance of lesions in such intractable variants of lupus erythematosus as the hypertrophic type and the infiltrative type so commonly seen on the eyelids.

The Problem of Reactive Manifestations

Reactions were recognized in the very beginnings of aurotherapy in this country. In a paper on the subject of aurotherapy read by me, in collaboration with Dr. Whitehouse, before the Section on Dermatology and Syphilology of the American Medical Association on May 19, 1927, only three months after the introduction of the method in the United States by Schamberg and Wright, nitritoid reactions from gold protein were reported in 1 case, and 2 cases presented a mild generalized vesicular dermatitis which soon cleared up. These were the only reactions observed in 37 patients receiving thirty to forty weekly injections of gold in doses of 100 mg. each. The nitritoid reactions in the case in which gold protein was used were believed by me to be caused by the protein in the compound and not by the gold. This belief was shared by Dr. Schamberg in a personal communication. Wright,²⁷ ten years later, stated that no immediate reactions had been noted either by him or by Schamberg after the substitution of gold sodium thiosulfate for the gold protein.

The classification of the various types of reaction made by Driver and Weller²⁸ in 1936, still excellent, follows: (1) immediate reactions, including anaphylactic reactions, febrile reactions, metallic taste in the mouth, and protein reactions to colloidal gold; (2) delayed toxic reactions, including stomatitis, gingivitis, hepatitis, digestive disturbances, and albuminuria; (3) reactions involving the skin; (4) death. Driver and Weller referred to 34 instances of death after the administration of gold compounds, but in this number are 21 deaths after the use of gold compounds given in large doses in advanced tuberculosis Morland and Zimmerli,²⁹ for example, reported a death in ten days after a single dose of 600 mg. of sanocrysin. Dumarest³⁰ and his coworkers reported a death following a single dose of 750 mg. of sanocrysin. Friedemann, Kwasniewski, and Deicher³¹ reported a death from apoplexy due, in their opinion, to activation of an old cerebral syphilis. This is an interesting observation in view of the fact that Ayres,³² in discussing the paper of Driver and Weller, reports an instance in which gold thiosulfate was used to obtain a provocative Wassermann reaction in a case in which the

diagnosis was in doubt. Ten days later, the previously negative Wassermann reaction was 4 plus. Ayres, in the same discussion, stated that he used the phenolsulfonphthalein test in order to detect renal insufficiency prior to the use of gold thiosulfate. He believed that he had saved himself from some bad results by this procedure.

Deducting the 21 deaths after the use of gold compounds in tuberculosis of the internal organs, which Driver and Weller state were due to the large doses used, we see in this same report 13 deaths attributed to the use of gold compounds in lupus erythematosus. Let us analyze them, eliminating the most improbable and submitting reasons for so doing. In 3 of the fatalities, death occurred after the administration of crisalbine (gold sodium thiosulfate): One death occurred after the injection of 600 mg. in the space of two weeks; the second death followed twelve weeks after five injections of 250 mg. each; in the third case the patient was given six injections of 100 to 500 mg. each, and ten months later, because of a recurrence of the lupus erythematosus, she received twenty injections of 250 mg. each. In these 3 cases reported by Gougerot and Burnier,³³ they themselves state that the fault of the drug was not conclusively proved. As Driver and Weller stated, the doses used were entirely too large. In another death³⁴ the fatal result followed the use of crisalbine in a case of lupus erythematosus disseminatus, in which in one week 170 mg. were given despite a febrile reaction and extension of the disease after each injection. The patient then received, at two-day intervals, injections of 1 mg., 2 mg., 5 mg., and 12 mg. each of aurophos. Despite severe prostration, three more milligrams were given. The patient died two days later. The reasons for death are too obvious to discuss. To give a gold compound in an acute disseminate lupus erythematosus and to continue its use in the face of severe reactive manifestations is only to court disaster.

Another case, reported by Jausion,³⁵ received six injections of crisalbine in doses of 250 to 500 mg. each at five-day intervals. Death followed in ten days. Jausion stated that in his opinion the doses were too large. Another death was observed by Mitchell³⁶ who gave a single injection (dosage not stated) of a gold compound to a patient with an acute disseminate erythematous lupus, and the patient died. The patient was in a hopeless condition before the injection, and Mitchell did not believe that the drug was responsible.

This leaves us then, out of a total of the 36 deaths, with 6 that can be clearly ascribed to gold sodium thiosulfate in the treatment of lupus erythematosus in the period between 1927 and 1931, the period of the greatest activity in aurotherapy. It is an extremely low death rate considering the fact that hundreds of cases of lupus erythematosus received thousands of injections of gold compounds in that space of time. Of course, a single death from such a source is deeply to be regretted, but is it not true that had we been deterred from using arsphenamine by the several hundred deaths that occurred early in its use we should have lost an invaluable aid in the treatment of syphilis? In my opinion, this holds equally true of gold. From an extensive personal experience I firmly believe that it still is the most efficacious remedy we possess in the treatment of lupus erythematosus and that accidents from its use can be greatly lessened by a careful watch for the occurrence of leukopenia, pruritus, dermatitis, and deficiency of kidney function. Gold should never be used in lupus erythematosus disseminatus of the acute variety with constitutional symptoms or in lupus erythematosus complicated by pulmonary tuberculosis because of the possible danger of activating the tuberculous processes. During aurotherapy, any excessive exposure to actinic light must be avoided. If any single one or a group of these contraindications appears during aurotherapy, it should be immediately discontinued.

Doses should be started at 5 mg., and in the absence of any of the above danger signals it can be raised weekly to 10, 25, or 50 mg. If progress is satisfactory, this dose need not be exceeded. Unfortunately, however, there are many cases that require doses of 100 mg. once a week to obtain maximum therapeutic results, and I have given such doses without accident in a great number of instances and over a considerable period of time.

May I close in the hope that I have been able to disperse some of the opprobrium under which aurotherapy is laboring at the present time. In my opinion it is wholly undeserved, since the remedy, used with due caution, has in my hands proved of the greatest value in lupus erythematosus, with no accidents in private practice and few in dispensary work.

Discussion

Dr. Rudolph Ruedemann, Jr., Albany, New York—A pinch hitter is always on the spot especially when opening a discussion extemporaneously on such an interesting timely subject, which Dr. Bechet has covered so thoroughly. He has left little to be added and I am 100 per cent in accord with the opinions expressed.

Gold treatment is somewhat on trial at present because of untoward reactions experienced in its use in arthritis. This has made itself felt in the management of lupus erythematosus—a tendency to reduce dosage. In this diminution good therapeutic results have suffered—many have turned to other forms of treatment. It is difficult to explain the reactions in arthritis. Dermatologists have been using this for about fifteen years in large doses with few severe reactions. In that period I can recall only two severe but not fatal reactions which necessitated cessa-

tion of treatment. Formerly, I gave 50 to 100 mg. without hesitation. Then came a period of conservatism which also influenced the arsenicals. I dropped to 10 to 25 mg. doses and the results were none too good. Recently, I have stepped up the dose of gold sodium thiosulfate with better results.

I can readily endorse Dr. Bechet's suggestion as to a thorough check-up before treatment is instituted and a careful observation during the treatment period. I always insist on a general check-up, which includes a complete blood examination and a chest x-ray.

In the interim, while undergoing examination,

I have the patient take his morning and evening temperatures. As a rule, reactions were found in patients showing an evening temperature rise.

It seems to be the rule to handle the subject of etiology with regard to lupus erythematosus with kid gloves if it is mentioned at all. I wish someone could definitely establish the relationship of tuberculosis to lupus erythematosus or vice versa.

It is an interesting worthwhile paper, and I am pleased that Dr. Bechet has again brought aurotherapy back into the therapeutic fold with dosage sufficient to give therapeutic results.

ACUTE SHORTAGE OF PSYCHIATRISTS

Quite apart from the contingency of war, psychiatry faces a great national emergency. One-half of the 500,000 hospital beds in this country are occupied by psychiatric patients; approximately 1,000 psychiatrists attempt to care for this vast group; while for all those cases of unhospitalized psychoses and the even greater number of neuroses and character disorders in the rest of the country's population there are only about 1,000 more psychiatrists. It is apparent that with this shortage of psychiatrists, good psychiatric care for millions of people who need it is not available. It is emphatically true, as Raymond B. Fosdick stated in his 1938 report to the Rockefeller Foundation, that mental hygiene represents one of the most underdeveloped areas in all medicine. "In no other field," he continued, "is the need more desperate or the potentialities for useful advances more promising. It is not necessary to recall the fact that cases of mental and nervous diseases occupy more hospital beds in this country than all other diseases combined. One has only to look about him at the tragic examples of human maladjustment and inadequacy in everyday life. Because the field is relatively so difficult, it has lagged far behind other developments in medicine."—*From The Bulletin of the Menninger Clinic*

THRIFT GUIDANCE TAUGHT IN SCHOOLS

There is already in America \$15,000,000 worth of evidence that the school children of today will know exactly what to do with their money if and when they become the millionaires of tomorrow. And, according to H. Thompson Rich, writing in the December issue of the magazine *Tomorrow*, the records of the American Bankers Association show that the "if" is not insurmountable. "Already three million pupils, in ten thousand schools, carry with American banks some fifteen million dollars, and educators envisage the day when thirty million pupils in one hundred thousand schools will boost that figure to a billion dollars."

This news seems miraculous. Moreover, Junior did it the "hard way." He ran errands, he dug in and made small sums in a hundred different ways, and then—this is the hard part—he put the money in the bank. A new subject, now being taught in the schools of forty states and the District of Columbia, was responsible for this. "Thrift Guidance," Mr. Rich writes, "is the textbook name of the subject. A natural outgrowth of the school bank idea, it now seeks a place on the curriculum along with manual training and domestic science. Tomorrow will see it compulsory in every tax-supported educational institution in the country."

TEN COMMANDMENTS FOR SUCCESSFUL GROUP CONFERENCE

The Eighth Health Education Institute that preceded the regular sessions of the seventeenth annual meeting of the American Public Health Association started off, as have its predecessors, with the wise idea of giving the leaders of the meetings some valuable suggestions on how best to make their group conferences a real exchange of ideas instead of degenerating, as so often happens in meetings of this kind, into rostrums where individuals may air their pet theories.

Dr. H. A. Overstreet, president, American Association for Adult Education, and professor emeritus of philosophy, College of the City of New York, gave an impromptu and informal talk

on how leaders of group conferences by the careful use of certain basic psychologic rules can focus the attention of participants on a logical, coordinated development of ideas and conclusions.

- 1 Make it a two-way process
- 2 Induce a sense of belonging
- 3 Be a weaver of thread of argument into a fabric
- 4 Bring out the shy
- 5 Keep down the voluble (without letting them know they are being kept down)
- 6 Never suppress anyone
- 7 Bring about a sense of accomplishment
- 8 Start from common experience
- 9 Have a sense of humor
- 10 Respect terminal facilities

INJURIES TO THE CERVICAL VERTEBRAE

BARBARA B. STIMSON, M.D., F.A.C.S., New York City*

THE number of articles on this subject appearing in the literature of both Europe and America in recent years bears witness to an awakened interest. No longer is a broken neck looked upon as a hopeless case to be treated by palliative means until such time as the inevitable outcome releases the victim. Application of the fundamental fracture principles of early reduction of deformity with adequate immobilization has brought about a change in point of view. Methods of reduction have been modified and improved, skeletal traction for these injuries has been devised, and operative fixation has been utilized in certain cases. Fatalities still occur, but permanent paralyses are less frequent and complete return of anatomy and function is no longer the exception.

Injuries to the cervical vertebrae can be caused by many types of accidents. Because of its mobility and its position above the relatively fixed thorax, the neck is particularly vulnerable. Dives into shallow pools, automobile accidents, and falls from a height are classic examples of causative factors. What is frequently overlooked, however, is the fact that far less dramatic traumas occurring when the cervical muscles are relaxed and off guard are responsible for many minor displacements of the cervical vertebrae which, if unrecognized and unreduced, may cause much subsequent discomfort to the patient. These milder forms will be discussed in the second part of the paper.

The mechanism of injury in the more severe types of displacement is usually that of flexion plus compression of the neck between head and thorax. With this there may also be a twisting or rotating force. There may result, therefore, complete dislocation either of one or of both articulating facets, with or without associated fracture, or there may be fracture without apparent dislocation—compression of a vertebral body, a cracked odontoid, a

fractured lamina or pedicle. No two cases are identical, for the combinations of possible injuries are obviously many.

Cord damage may be caused by the initial injury, by mechanical pressure of the displaced bone, by hemorrhage, or by edema. It may be complete or partial, progressive or retrogressive. The treatment will not be discussed, except insofar as it is included in the treatment of the bone lesion.
